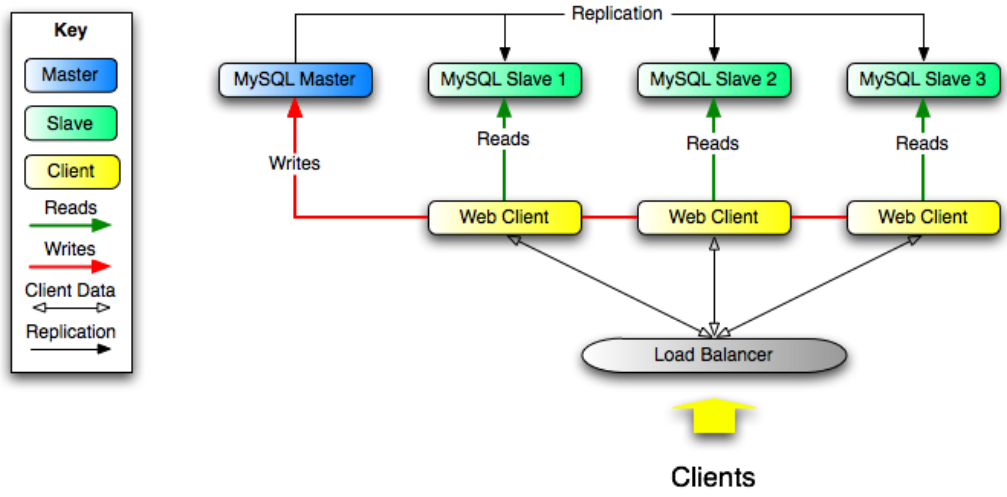
Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most websites fit into this category, where users are browsing the website, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in Figure 17.1, “Using Replication to Improve Performance During Scale-Out”.

Figure 17.1 Using Replication to Improve Performance During Scale-Out



If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take

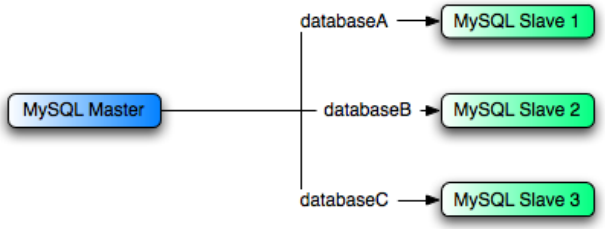
advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by writing a conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

17.3.6 Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in Figure 17.2, “Using Replication to Replicate Databases to Separate Replication Slaves”.

Figure 17.2 Using Replication to Replicate Databases to Separate Replication Slaves



You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

Important

You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in Figure 17.2, “Using Replication to Replicate Databases to Separate Replication Slaves”, you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

Note

This does not work with `InnoDB` databases unless you use `innodb_file_per_table`.

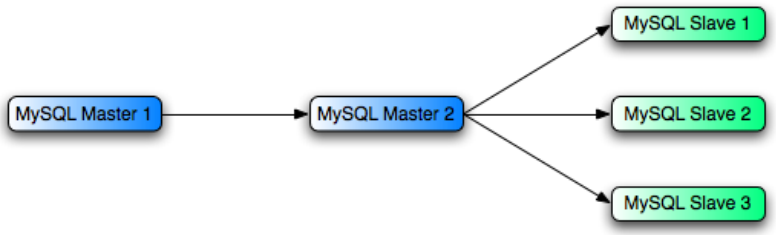
17.3.7 Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in Figure 17.3, “Using an Additional Replication Host to Improve Performance”.

Figure 17.3 Using an Additional Replication Host to Improve Performance



For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging is enabled on both masters, which is the default.
- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1. Master 2 has the `--log-slave-updates` option enabled (which is the default). With this option, replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.
- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.

- If heavy disk I/O activity for reads of the binary log file and relay log files is an issue, consider increasing the value of the `rpl_read_size` system variable. This system variable controls the minimum amount of data read from the log files, and increasing it might reduce file reads and I/O stalls when the file data is not currently cached by the operating system. Note that a buffer the size of this value is allocated for each thread that reads from the binary log and relay log files, including dump threads on masters and coordinator threads on slaves. Setting a large value might therefore have an impact on memory consumption for servers.

- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See Section 17.3.6, “Replicating Different Databases to Different Slaves”.

- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use `MyISAM` or another nontransactional engine on the slaves. See Section 17.3.4, “Using Replication with Different Master and Slave Storage Engines”.

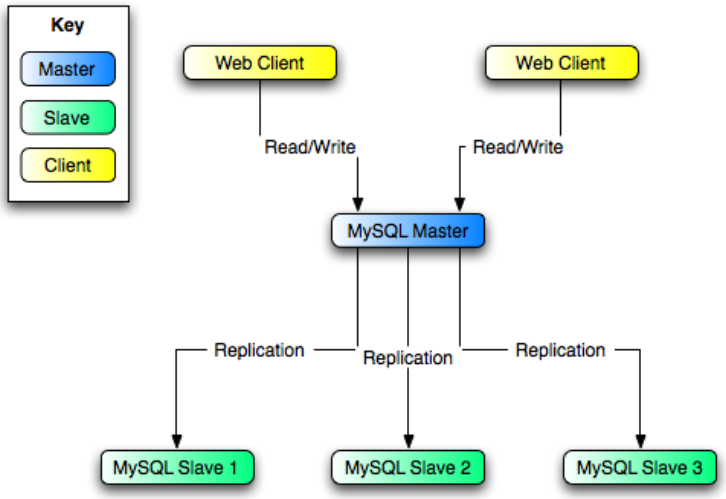
- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you may switch off `--log-slave-updates` on the slaves. This prevents “dumb” slaves from also logging events they have executed into their own binary log.

17.3.8 Switching Masters During Failover

You can tell a slave to change to a new master using the `CHANGE MASTER TO` statement. The slave does not check whether the databases on the master are compatible with those on the slave; it simply begins reading and executing events from the specified coordinates in the new master's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Slaves should be run with binary logging enabled (the `--log-bin` option), which is the default. If you are not using GTIDs for replication, then the slaves should also be run with `--skip-log-slave-updates` (logging slave updates is the default). In this way, the slave is ready to become a master without restarting the slave `mysqld`. Assume that you have the structure shown in Figure 17.4, “Redundancy Using Replication, Initial Structure”.

Figure 17.4 Redundancy Using Replication, Initial Structure



In this diagram, the `MySQL Master` holds the master database, the `MySQL Slave` hosts are replication slaves, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not

need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see Section 17.3.5, “Using Replication for Scale-Out”.

Each MySQL Slave (`Slave 1`, `Slave 2`, and `Slave 3`) is a slave running with binary logging enabled, and with `--skip-log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log when `--skip-log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason `MySQL Master` becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick `Slave 1`, all `Web Clients` should be redirected to `Slave 1`, which writes the updates to its binary log. `Slave 2` and `Slave 3` should then replicate from `Slave 1`.

The reason for running the slave with `--skip-log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. If `Slave 1` has `--log-slave-updates` enabled, which is the default, it writes any updates that it receives from `Master` in its own binary log. This means that, when `Slave 2` changes from `Master` to `Slave 1` as its master, it may receive updates from `Slave 1` that it has already received from `Master`.

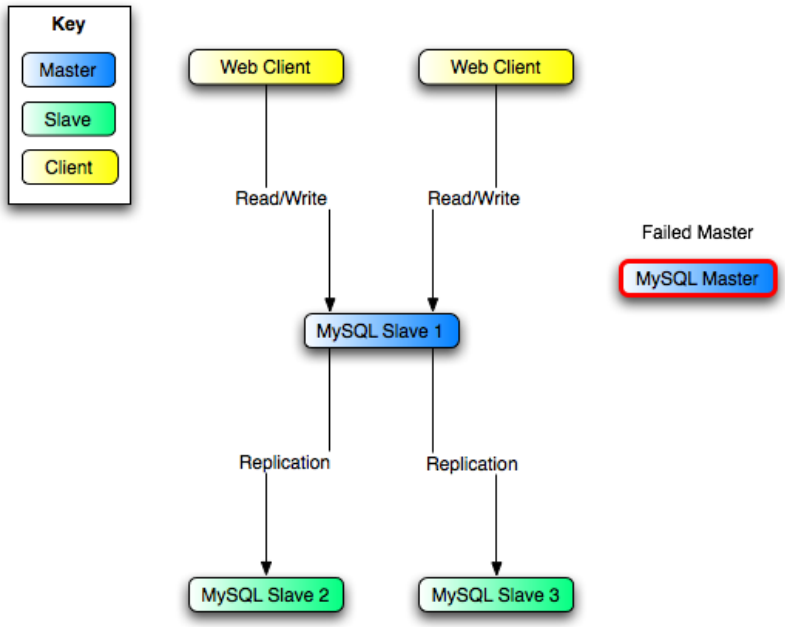
Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `'Slave1'` represents the real host name of `Slave 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (*`user`*, *`password`*, *`port`*). When issuing the `CHANGE MASTER TO` statement in this, there is no need to specify the name of the `Slave 1` binary log file or log position to read from, since the first binary log file and position 4, are the defaults. Finally, execute `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication setup is in place, you need to tell each `Web Client` to direct its statements to `Slave 1`. From that point on, all update statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in Figure 17.5, “Redundancy Using Replication, After Master Failure”.

Figure 17.5 Redundancy Using Replication, After Master Failure



When `Master` becomes available again, you should make it a slave of `Slave 1`. To do this, issue on `Master` the same `CHANGE MASTER TO` statement as that issued on `Slave 2` and `Slave 3` previously. `Master` then becomes a slave of `S1ave 1` and picks up the `Web Client` writes that it missed while it was offline.

To make `Master` a master again, use the preceding procedure as if `Slave 1` was unavailable and `Master` was to be the new master. During this procedure, do not forget to run `RESET MASTER` on `Master` before making `Slave 1`, `Slave 2`, and `Slave 3` slaves of `Master`. If you fail to do this, the slaves may pick up stale writes from the `Web Client` applications dating from before the point at which `Master` became unavailable.

You should be aware that there is no synchronization between slaves, even when they share the same master, and thus some slaves might be considerably ahead of others. This means that in some cases the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all slaves should be relatively close together.

One way to keep applications informed about the location of the master is to have a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to update the DNS dynamically.

17.3.9 Setting Up Replication to Use Encrypted Connections

To use an encrypted connection for the transfer of the binary log required during replication, both the master and the slave servers must support encrypted network connections. If either server does not support encrypted connections (because it has not been compiled or configured for them), replication through an encrypted connection is not possible.

Setting up encrypted connections for replication is similar to doing so for client/server connections. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave. You must also obtain suitable key files.

For more information on setting up a server and client for encrypted connections, see Section 6.4.1, “Configuring MySQL to Use Encrypted Connections”.

To enable encrypted connections on the master, you must create or obtain suitable certificate and key files, and then add the following configuration options to the master's configuration within the `[mysqld]` section of the master's `my.cnf` file, changing the file names as necessary:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the files may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- `--ssl-ca`: The path name of the Certificate Authority (CA) certificate file. (`--ssl-capath` is similar but specifies the path name of a directory of CA certificate files.)
- `--ssl-cert`: The path name of the server public key certificate file. This can be sent to the client and authenticated against the CA certificate that it has.
- `--ssl-key`: The path name of the server private key file.

To enable encrypted connections on the slave, use the `CHANGE MASTER TO` statement. You can either name the slave certificate and SSL private key files required for the encrypted connection in the `[client]` section of the slave's `my.cnf` file, or you can explicitly specify that information using the `CHANGE MASTER TO` statement. For more information on the `CHANGE MASTER TO` statement, see Section 13.4.2.1, “CHANGE MASTER TO Syntax”.

- To name the slave certificate and key files using an option file, add the following lines to the `[client]` section of the slave's `my.cnf` file, changing the file names as necessary:

```
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
ssl-key=client-key.pem
```

- Restart the slave server, using the `--skip-slave-start` option to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, and add the `MASTER_SSL` option to connect using encryption:

```
mysql> CHANGE MASTER TO
    -> MASTER_HOST='master_hostname',
    -> MASTER_USER='repl',
    -> MASTER_PASSWORD='password',
    -> MASTER_SSL=1;
```

  Setting `MASTER_SSL=1` for a replication connection and then setting no further `MASTER_SSL_xxx` options corresponds to setting `--ssl-mode=REQUIRED` for the client, as described in Section 6.4.2, “Command Options for Encrypted Connections”. With `MASTER_SSL=1`, the connection attempt only succeeds if an encrypted connection can be established. A replication connection does not fall back to an unencrypted connection, so there is no setting corresponding to the `--ssl-mode=PREFERRED` setting for replication. If `MASTER_SSL=0` is set, this corresponds to `--ssl-mode=DISABLED`.

- To name the slave certificate and SSL private key files using the `CHANGE MASTER TO` statement, if you did not do this in the slave's `my.cnf` file, add the appropriate `MASTER_SSL_xxx` options:

```
    -> MASTER_SSL_CA = 'ca_file_name',
    -> MASTER_SSL_CAPATH = 'ca_directory_name',
    -> MASTER_SSL_CERT = 'cert_file_name',
    -> MASTER_SSL_KEY = 'key_file_name',
```

  These options correspond to the `--ssl-xxx` options with the same names, as described in Section 6.4.2, “Command Options for Encrypted Connections”. For these options to take effect, `MASTER_SSL=1` must also be set. For a replication connection, specifying a value for either of `MASTER_SSL_CA` or `MASTER_SSL_CAPATH`, or specifying these options in the slave's `my.cnf` file, corresponds to setting `--ssl-mode=VERIFY_CA`. The connection attempt only succeeds if a valid matching Certificate Authority (CA) certificate is found using the specified information.

- To activate host name identity verification, add the `MASTER_SSL_VERIFY_SERVER_CERT` option:

```
    -> MASTER_SSL_VERIFY_SERVER_CERT=1,
```

  This option corresponds to the `--ssl-verify-server-cert` option, which was deprecated from MySQL 5.7 and removed in MySQL 8.0. For a replication connection, specifying `MASTER_SSL_VERIFY_SERVER_CERT=1` corresponds to setting `--ssl-mode=VERIFY_IDENTITY`, as described in Section 6.4.2, “Command Options for Encrypted Connections”. For this option to take effect, `MASTER_SSL=1` must also be set. Host name identity verification does not work with self-signed certificates.

- To activate certificate revocation list (CRL) checks, add the `MASTER_SSL_CRL` or `MASTER_SSL_CRLPATH` option:

```
    -> MASTER_SSL_CRL = 'crl_file_name',
    -> MASTER_SSL_CRLPATH = 'crl_directory_name',
```

  These options correspond to the `--ssl-xxx` options with the same names, as described in Section 6.4.2, “Command Options for Encrypted Connections”. If they are not specified, no CRL checking takes place.

- To specify lists of permitted ciphers and encryption protocols for the replication connection, add the `MASTER_SSL_CIPHER` and `MASTER_TLS_VERSION` options:

```
    -> MASTER_SSL_CIPHER = 'cipher_list',
    -> MASTER_TLS_VERSION = 'protocol_list',
```

  The `MASTER_SSL_CIPHER` option specifies the list of permitted ciphers for the replication connection, with one or more cipher names separated by colons. The `MASTER_TLS_VERSION` option specifies the encryption protocols permitted for the replication connection. The format is like that for the `tls_version` system variable, with one or more protocol names separated by commas. The protocols and ciphers that you can use in these lists depend on the SSL library used to compile MySQL. For information about the formats and permitted values, see Section 6.4.6, “Encrypted Connection Protocols and Ciphers”.

- After the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

  You can use the `SHOW SLAVE STATUS` statement to confirm that an encrypted connection was established successfully.

- Requiring encrypted connections on the slave does not ensure that the master requires encrypted connections from slaves. If you want to ensure that the master only accepts replication slaves that connect using encrypted connections, create a replication user account on the master using the `REQUIRE SSL` option, then grant that user the `REPLICATION SLAVE` privilege. For example:

```
mysql> CREATE USER 'repl'@'%.example.com' IDENTIFIED BY 'password'
    -> REQUIRE SSL;
mysql> GRANT REPLICATION SLAVE ON *.*
    -> TO 'repl'@'%.example.com';
```

  If you have an existing replication user account on the master, you can add `REQUIRE SSL` to it with this statement:

```
mysql> ALTER USER 'repl'@'%.example.com' REQUIRE SSL;
```

17.3.10 Encrypting Binary Log Files and Relay Log Files

From MySQL 8.0.14, binary log files and relay log files can be encrypted, helping to protect these files and the potentially sensitive data contained in them from being misused by outside attackers, and also from unauthorized viewing by users of the operating system where they are stored. The encryption algorithm used for the files, the AES (Advanced Encryption Standard) cipher algorithm, is built in to MySQL Server and cannot be configured. Binary log encryption is supported for OpenSSL and wolfSSL builds of MySQL Server.

You enable this encryption on a MySQL server by setting the `binlog_encryption` system variable to `ON`. `OFF` is the default. The system variable sets encryption on for binary log files and relay log files. Binary logging does not need to be enabled on the server to enable encryption, so you can encrypt the relay log files on a slave that has no binary log. To use encryption, a keyring plugin must be installed and configured to supply MySQL Server's keyring service. For instructions to do this, see Section 6.5.4, “The MySQL Keyring”. Any supported keyring plugin can be used to store binary log encryption keys.

When you first start the server with encryption enabled, a new binary log encryption key is generated before the binary log and relay logs are initialized. This key is used to encrypt a file password for each binary log file (if the server has binary logging enabled) and relay log file (if the server has replication channels), and further keys generated from the file passwords are used to encrypt the data in the files. The binary log encryption key that is currently in use on the server is called the binary log master key. The two tier encryption key architecture means that the binary log master key can be rotated (replaced

by a new master key) as required, and only the file password for each file needs to be re-encrypted with the new master key, not the whole file. Relay log files are encrypted for all channels, including new channels that are created after encryption is activated. The binary log index file and relay log index file are never encrypted.

If you activate encryption while the server is running, a new binary log encryption key is generated at that time. The exception is if encryption was active previously on the server and was then disabled, in which case the binary log encryption key that was in use before is used again. The binary log file and relay log files are rotated immediately, and file passwords for the new files and all subsequent binary log files and relay log files are encrypted using this binary log encryption key. Existing binary log files and relay log files still present on the server are not encrypted, but you can purge them if they are no longer needed.

If you deactivate encryption by changing the `binlog_encryption` system variable to `OFF`, the binary log file and relay log files are rotated immediately and all subsequent logging is unencrypted. Previously encrypted files are not automatically decrypted, but the server is still able to read them. The `BINLOG_ENCRYPTION_ADMIN` privilege is required to activate or deactivate encryption while the server is running.

Encrypted and unencrypted binary log files can be distinguished using the magic number at the start of the file header for encrypted log files (`0xFD62696E`), which differs from that used for unencrypted log files (`0xFE62696E`). The `SHOW BINARY LOGS` statement shows whether each binary log file is encrypted or unencrypted.

Note that when encryption is active for a MySQL server instance, only the data at rest that is written to the binary log files and relay log files is encrypted. The data in motion in the replication event stream, which is sent to MySQL clients including `mysqlbinlog`, is always in unencrypted format, so it must be protected in transit by the use of connection encryption (see Section 6.4, “Using Encrypted Connections”). The data in use that is held in the binary log transaction and statement caches during a transaction, and any data that exceeds the space available in those caches and is therefore stored in a temporary file on disk, is also in unencrypted format. The temporary files and caches are deleted when the thread that handles the transaction ends. The server status variables `Binlog_cache_disk_use` and `Binlog_stmt_cache_disk_use` show whether any data has been stored in temporary files, and you can increase the size of the binary log cache or binary log statement cache if you want to minimize the possibility of having unencrypted temporary files for the duration of a transaction.

When binary log files have been encrypted, `mysqlbinlog` cannot read them directly, but can read them from the server using the `--read-from-remote-server` option. From MySQL 8.0.14, `mysqlbinlog` returns a suitable error if you attempt to read an encrypted binary log file directly, but older versions of `mysqlbinlog` do not recognise the file as a binary log file at all. If you back up encrypted binary log files using `mysqlbinlog`, note that the copies of the files that are generated using `mysqlbinlog` are stored in an unencrypted format.

Binary log encryption keys

The binary log encryption keys used to encrypt the file passwords for the log files are 256-bit keys that are generated specifically for each MySQL server instance using MySQL Server's keyring service (see Section 6.5.4, “The MySQL Keyring”). The keyring service handles the creation, retrieval, and deletion of the binary log encryption keys. A server instance only creates and removes keys generated for itself, but it can read keys generated for other instances if they are stored in the keyring, as in the case of a server instance that has been cloned by file copying.

Important

The binary log encryption keys for a MySQL server instance must be included in your backup and recovery procedures, because if the keys required to decrypt the file passwords for current and retained binary log files or relay log files are lost, it might not be possible to start the server.

The format of binary log encryption keys in the keyring is as follows:

```
MySQLReplicationKey_{UUID}_{SEQ_NO}
```

For example:

```
MySQLReplicationKey_00508583-b5ce-11e8-a6a5-0010e0734796_1
```

`{UUID}` is the true UUID generated by the MySQL server (the value of the `server_uuid` system variable). `{SEQ_NO}` is the sequence number for the binary log encryption key, which is incremented by 1 for each new key that is generated on the server.

The binary log encryption key that is currently in use on the server is called the binary log master key. The sequence number for the current binary log master key is stored in the keyring. The binary log master key is used to encrypt each new log file's file password, which is a randomly generated 32-byte file password specific to the log file that is used to encrypt the file data. The file password is encrypted using AES-CBC (AES Cipher Block Chaining mode) with the 256-bit binary log encryption key and a random initialization vector (IV), and is stored in the log file's file header. The file data is encrypted using AES-CTR (AES Counter mode) with a 256-bit key generated from the file password and a nonce also generated from the file password. It is technically possible to decrypt an encrypted file offline, if the binary log encryption key used to encrypt the file password is known, by using tools available in the OpenSSL cryptography toolkit.

If you use file copying to clone a MySQL server instance that has encryption active so its binary log files and relay log files are encrypted, ensure that the keyring is also copied, so that the clone server can read the binary log encryption keys from the source server. When encryption is activated on the clone server (either at startup or subsequently), the clone server recognizes that the binary log encryption keys used with the copied files include the generated UUID of the source server. It automatically generates a new binary log encryption key using its own generated UUID, and uses this to encrypt the file passwords for subsequent binary log files and relay log files. The copied files continue to be read using the source server's keys.

Master key rotation

When binary log encryption is enabled, you can rotate the binary log master key at any time while the server is running by issuing `ALTER INSTANCE ROTATE BINLOG MASTER KEY`. When the binary log master key is rotated manually using this statement, the passwords for the new and subsequent files are encrypted using the new binary log master key, and also the file passwords for existing encrypted binary log files and relay log files are re-encrypted using the new binary log master key, so the encryption is renewed completely. You can rotate the binary log master key on a regular basis to comply with your organization's security policy, and also if you suspect that the current or any of the previous binary log master keys might have been compromised.

When you rotate the binary log master key manually, MySQL Server takes the following actions in sequence:

1. A new binary log encryption key is generated with the next available sequence number, stored on the keyring, and used as the new binary log master key.
2. The binary log and relay log files are rotated on all channels.
3. The new binary log master key is used to encrypt the file passwords for the new binary log and relay log files, and subsequent files until the key is changed again.
4. The file passwords for existing encrypted binary log files and relay log files on the server are re-encrypted in turn using the new binary log master key, starting with the most recent files. Any unencrypted files are skipped.
5. Binary log encryption keys that are no longer in use for any files after the re-encryption process are removed from the keyring.

The `BINLOG_ENCRYPTION_ADMIN` privilege is required to issue `ALTER INSTANCE ROTATE BINLOG MASTER KEY`, and the statement cannot be used if the `binlog_encryption` system variable is set to `OFF`.

As the final step of the binary log master key rotation process, all binary log encryption keys that no longer apply to any retained binary log files or relay log files are cleaned up from the keyring. If a retained binary log file or relay log file cannot be initialized for re-encryption, the relevant binary log encryption keys are not deleted in case the files can be recovered in the future. For example, this might be the case if a file listed in a binary log index file is currently unreadable, or if a channel fails to initialize. If the server UUID changes, for example because a backup created using MySQL Enterprise Backup is used to set up a new replication slave, issuing `ALTER INSTANCE ROTATE BINLOG MASTER KEY` on the new server does not delete any earlier binary log encryption keys that include the original server UUID.

If any of the first four steps of the binary log master key rotation process cannot be completed correctly, an error message is issued explaining the situation and the consequences for the encryption status of the binary log files and relay log files. Files that were previously encrypted are always left in an encrypted state, but their file passwords might still be encrypted using an old binary log master key. If you see these errors, first retry the process by issuing `ALTER INSTANCE ROTATE BINLOG MASTER KEY` again. Then investigate the status of individual files to see what is blocking the process, especially if you suspect that the current or any of the previous binary log master keys might have been compromised.

If the final step of the binary log master key rotation process cannot be completed correctly, a warning message is issued explaining the situation. The warning message identifies whether the process could not clean up the auxiliary keys in the keyring for rotating the binary log master key, or could not clean up older unused binary log master keys. You can choose to ignore the message as the keys are auxiliary keys or no longer in use, or you can issue `ALTER INSTANCE ROTATE BINLOG MASTER KEY` again to retry the process.

If the server stops and is restarted with binary log encryption still set to `ON` during the binary log master key rotation process, new binary log files and relay log files after the restart are encrypted using the new binary log master key. However, the re-encryption of existing files is not continued, so files that did not get re-encrypted before the server stopped are left encrypted using the previous binary log master key. To complete re-encryption and clean up unused binary log encryption keys, issue `ALTER INSTANCE ROTATE BINLOG MASTER KEY` again after the restart.

`ALTER INSTANCE ROTATE BINLOG MASTER KEY` actions are not written to the binary log and are not executed on replication slaves. Binary log master key rotation can therefore be carried out in replication environments including a mix of MySQL versions. To schedule regular rotation of the binary log master key on all applicable master and slave servers, you can enable the MySQL Event Scheduler on each server and issue the `ALTER INSTANCE ROTATE BINLOG MASTER KEY` statement using a `CREATE EVENT` statement. If you rotate the binary log master key because you suspect that the current or any of the previous binary log master keys might have been compromised, issue the statement on every applicable master and slave server. Issuing the statement on individual servers ensures that you can verify immediate compliance, even in the case of slaves that are lagging, belong to multiple replication topologies, or are not currently active in the replication topology but have binary log and relay log files.

The `binlog_rotate_encryption_master_key_at_startup` system variable controls whether the binary log master key is automatically rotated when the server is restarted. If this system variable is set to `ON`, a new binary log encryption key is generated and used as the new binary log master key whenever the server is restarted. If it is set to `OFF`, which is the default, the existing binary log master key is used again after the restart. When the binary log master key is rotated at startup, the file passwords for the new binary log and relay log files are encrypted using the new key. The file passwords for the existing encrypted binary log files and relay log files are not re-encrypted, so they remain encrypted using the old key, which remains available on the keyring.

17.3.11 Semisynchronous Replication

In addition to the built-in asynchronous replication, MySQL 8.0 supports an interface to semisynchronous replication that is implemented by plugins. This section discusses what

semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.

MySQL replication by default is asynchronous. The master writes events to its binary log but does not know whether or when a slave has retrieved and processed them. With asynchronous replication, if the master crashes, transactions that it has committed might not have been transmitted to any slave. Consequently, failover from master to slave in this case may result in failover to a server that is missing transactions relative to the master.

Semisynchronous replication can be used as an alternative to asynchronous replication:

- A slave indicates whether it is semisynchronous-capable when it connects to the master.
- If semisynchronous replication is enabled on the master side and there is at least one semisynchronous slave, a thread that performs a transaction commit on the master blocks and waits until at least one semisynchronous slave acknowledges that it has received all events for the transaction, or until a timeout occurs.
- The slave acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.
- If a timeout occurs without any slave having acknowledged the transaction, the master reverts to asynchronous replication. When at least one semisynchronous slave catches up, the master returns to semisynchronous replication.
- Semisynchronous replication must be enabled on both the master and slave sides. If semisynchronous replication is disabled on the master, or enabled on the master but on no slaves, the master uses asynchronous replication.

While the master is blocking (waiting for acknowledgment from a slave), it does not return to the session that performed the transaction. When the block ends, the master returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the master side, and receipt of its events has been acknowledged by at least one slave.

The number of slave acknowledgments the master must receive per transaction before proceeding is configurable using the `rpl_semi_sync_master_wait_for_slave_count` system variable. The default value is 1.

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to slaves.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement commits implicitly. With semisynchronous replication, the master blocks for each such statement, just as it does for explicit transaction commits.

To understand what the “semi” in “semisynchronous replication” means, compare it with asynchronous and fully synchronous replication:

- With asynchronous replication, the master writes events to its binary log and slaves request them when they are ready. There is no guarantee that any event will ever reach any slave.
- With fully synchronous replication, when a master commits a transaction, all slaves also will have committed the transaction before the master returns to the session that performed the transaction. The drawback of this is that there might be a lot of delay to complete a transaction.
- Semisynchronous replication falls between asynchronous and fully synchronous replication. The master waits only until at least one slave has received and logged the events. It does not wait for all slaves to acknowledge receipt, and it requires only receipt, not that the events have been fully executed and committed on the slave side.

Compared to asynchronous replication, semisynchronous replication provides improved data integrity because when a commit returns successfully, it is known that the data exists in at least two places. Until a semisynchronous master receives acknowledgment from the number of slaves configured by `rpl_semi_sync_master_wait_for_slave_count`, the transaction is on hold and not committed.

Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from master to slave. When one user is too busy, this will slow it down, which is useful in some deployment situations.

Semisynchronous replication does have some performance impact because commits are slower due to the need to wait for slaves. This is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to send the commit to the slave and wait for the acknowledgment of receipt by the slave. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks.

The `rpl_semi_sync_master_wait_point` system variable controls the point at which a semisynchronous replication master waits for slave acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- `AFTER_SYNC` (the default): The master writes each transaction to its binary log and the slave, and syncs the binary log to disk. The master waits for slave acknowledgment of transaction receipt after the sync. Upon receiving acknowledgment, the master commits the transaction to the storage engine and returns a result to the client, which then can proceed.
- `AFTER_COMMIT`: The master writes each transaction to its binary log and the slave, syncs the binary log, and commits the transaction to the storage engine. The master waits for slave acknowledgment of transaction receipt after the commit. Upon receiving acknowledgment, the master returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:

- With `AFTER_SYNC`, all clients see the committed transaction at the same time: After it has been acknowledged by the slave and committed to the storage engine on the master. Thus, all clients see the same data on the master.

  In the event of master failure, all transactions committed on the master have been replicated to the slave (saved to its relay log). A crash of the master and failover to the slave is lossless because the slave is up to date.

- With `AFTER_COMMIT`, the client issuing the transaction gets a return status only after the server commits to the storage engine and receives slave acknowledgment. After the commit and before slave acknowledgment, other clients can see the committed transaction before the committing client.

  If something goes wrong such that the slave does not process the transaction, then in the event of a master crash and failover to the slave, it is possible that such clients will see a loss of data relative to what they saw on the master.

17.3.11.1 Semisynchronous Replication Administrative Interface

The administrative interface to semisynchronous replication has several components:

- Two plugins implement semisynchronous capability. There is one plugin for the master side and one for the slave side.
- System variables control plugin behavior. Some examples:
  - `rpl_semi_sync_master_enabled`

    Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 0 (off).

- `rpl_semi_sync_master_timeout`

  A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

- `rpl_semi_sync_slave_enabled`

  Similar to `rpl_semi_sync_master_enabled`, but controls the slave plugin.

All `rpl_semi_sync_xxx` system variables are described at Section 5.1.8, “Server System Variables”.

- Status variables enable semisynchronous replication monitoring. Some examples:

  - `Rpl_semi_sync_master_clients`

    The number of semisynchronous slaves.

  - `Rpl_semi_sync_master_status`

    Whether semisynchronous replication currently is operational on the master. The value is 1 if the plugin has been enabled and a commit acknowledgment has not occurred. It is 0 if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

  - `Rpl_semi_sync_master_no_tx`

    The number of commits that were not acknowledged successfully by a slave.

  - `Rpl_semi_sync_master_yes_tx`

    The number of commits that were acknowledged successfully by a slave.

  - `Rpl_semi_sync_slave_status`

    Whether semisynchronous replication currently is operational on the slave. This is 1 if the plugin has been enabled and the slave I/O thread is running, 0 otherwise.

  All `Rpl_semi_sync_xxx` status variables are described at Section 5.1.10, “Server Status Variables”.

The system and status variables are available only if the appropriate master or slave plugin has been installed with `INSTALL PLUGIN`.

17.3.11.2 Semisynchronous Replication Installation and Configuration

Semisynchronous replication is implemented using plugins, so the plugins must be installed into the server to make them available. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are unavailable until the associated plugin has been installed.

This section describes how to install the semisynchronous replication plugins. For general information about installing plugins, see Section 5.6.1, “Installing and Uninstalling Plugins”.

To use semisynchronous replication, the following requirements must be satisfied:

- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.
- Replication must already be working, see Section 17.1, “Configuring Replication”.

- There must not be multiple replication channels configured. Semisynchronous replication is only compatible with the default replication channel. See Section 17.2.3, “Replication Channels”.

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP SLAVE`, and `START SLAVE` statements mentioned here require the `REPLICATION_SLAVE_ADMIN` or `SUPER` privilege.

MySQL distributions include semisynchronous replication plugin files for the master side and the slave side.

To be usable by a master or slave server, the appropriate plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base names are `semisync_master` and `semisync_slave`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

The master plugin library file must be present in the plugin directory of the master server. The slave plugin library file must be present in the plugin directory of each slave server.

To load the plugins, use the `INSTALL PLUGIN` statement on the master and on each slave that is to be semisynchronous (adjust the `.so` suffix for your platform as necessary).

On the master:

```
INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
```

On each slave:

```
INSTALL PLUGIN rpl_semi_sync_slave SONAME 'semisync_slave.so';
```

If an attempt to install a plugin results in an error on Linux similar to that shown here, you must install `libimf`:

```
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
ERROR 1126 (HY000): Can't open shared library
'/usr/local/mysql/lib/plugin/semisync_master.so'
(errno: 22 libimf.so: cannot open shared object file:
No such file or directory)
```

You can obtain `libimf` from https://dev.mysql.com/downloads/os-linux.html.

To see which plugins are installed, use the `SHOW PLUGINS` statement, or query the `INFORMATION_SCHEMA.PLUGINS` table.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.6.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
       FROM INFORMATION_SCHEMA.PLUGINS
       WHERE PLUGIN_NAME LIKE '%semi%';
+----------------------+---------------+
| PLUGIN_NAME          | PLUGIN_STATUS |
+----------------------+---------------+
| rpl_semi_sync_master | ACTIVE        |
+----------------------+---------------+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

After a semisynchronous replication plugin has been installed, it is disabled by default. The plugins must be enabled both on the master side and the slave side to enable semisynchronous replication. If only one side is enabled, replication will be asynchronous.

To control whether an installed plugin is enabled, set the appropriate system variables. You can set these variables at runtime using `SET GLOBAL`, or at server startup on the command line or in an option file.

At runtime, these master-side system variables are available:

```
SET GLOBAL rpl_semi_sync_master_enabled = {0|1};
SET GLOBAL rpl_semi_sync_master_timeout = N;
```

On the slave side, this system variable is available:

```
SET GLOBAL rpl_semi_sync_slave_enabled = {0|1};
```

For `rpl_semi_sync_master_enabled` or `rpl_semi_sync_slave_enabled`, the value should be 1 to enable semisynchronous replication or 0 to disable it. By default, these variables are set to 0.

For `rpl_semi_sync_master_timeout`, the value *N* is given in milliseconds. The default value is 10000 (10 seconds).

If you enable semisynchronous replication on a slave at runtime, you must also start the slave I/O thread (stopping it first if it is already running) to cause the slave to connect to the master and register as a semisynchronous slave:

```
STOP SLAVE IO_THREAD;
START SLAVE IO_THREAD;
```

If the I/O thread is already running and you do not restart it, the slave continues to use asynchronous replication.

At server startup, the variables that control semisynchronous replication can be set as command-line options or in an option file. A setting listed in an option file takes effect each time the server starts. For example, you can set the variables in `my.cnf` files on the master and slave sides as follows.

On the master:

```
[mysqld]
rpl_semi_sync_master_enabled=1
rpl_semi_sync_master_timeout=1000 # 1 second
```

On each slave:

```
[mysqld]
rpl_semi_sync_slave_enabled=1
```

17.3.11.3 Semisynchronous Replication Monitoring

The plugins for the semisynchronous replication capability expose several system and status variables that you can examine to determine its configuration and operational state.

The system variable reflect how semisynchronous replication is configured. To check their values, use `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'rpl_semi_sync%';
```

The status variables enable you to monitor the operation of semisynchronous replication. To check their values, use `SHOW STATUS`:

```
mysql> SHOW STATUS LIKE 'Rpl_semi_sync%';
```

When the master switches between asynchronous or semisynchronous replication due to commit-blocking timeout or a slave catching up, it sets the value of the `Rpl_semi_sync_master_status`

status variable appropriately. Automatic fallback from semisynchronous to asynchronous replication on the master means that it is possible for the `rpl_semi_sync_master_enabled` system variable to have a value of 1 on the master side even when semisynchronous replication is in fact not operational at the moment. You can monitor the `Rpl_semi_sync_master_status` status variable to determine whether the master currently is using asynchronous or semisynchronous replication.

To see how many semisynchronous slaves are connected, check `Rpl_semi_sync_master_clients`.

The number of commits that have been acknowledged successfully or unsuccessfully by slaves are indicated by the `Rpl_semi_sync_master_yes_tx` and `Rpl_semi_sync_master_no_tx` variables.

On the slave side, `Rpl_semi_sync_slave_status` indicates whether semisynchronous replication currently is operational.

17.3.12 Delayed Replication

MySQL supports delayed replication such that a slave server deliberately executes transactions later than the master by at least a specified amount of time. This section describes how to configure a replication delay on a slave, and how to monitor replication delay.

In MySQL 8.0, the method of delaying replication depends on two timestamps, `immediate_commit_timestamp` and `original_commit_timestamp` (see Replication Delay Timestamps). If all servers in the replication topology are running MySQL 8.0.1 or above, delayed replication is measured using these timestamps. If either the immediate master or slave is not using these timestamps, the implementation of delayed replication from MySQL 5.7 is used (see Delayed Replication). This section describes delayed replication between servers which are all using these timestamps.

The default replication delay is 0 seconds. Use the `CHANGE MASTER TO MASTER_DELAY=N` statement to set the delay to *`N`* seconds. A transaction received from the master is not executed until at least *`N`* seconds later than its commit on the immediate master. The delay happens per transaction (not event as in previous MySQL versions) and the actual delay is imposed only on `gtid_log_event` or `anonymous_gtid_log_event`. The other events in the transaction always follow these events without any waiting time imposed on them.

Note

`START SLAVE` and `STOP SLAVE` take effect immediately and ignore any delay. `RESET SLAVE` resets the delay to 0.

The `replication_applier_configuration` Performance Schema table contains the `DESIRED_DELAY` column which shows the delay configured using the `MASTER_DELAY` option. The `replication_applier_status` Performance Schema table contains the `REMAINING_DELAY` column which shows the number of delay seconds remaining.

Delayed replication can be used for several purposes:

- To protect against user mistakes on the master. With a delay you can roll back a delayed slave to the time just before the mistake.
- To test how the system behaves when there is a lag. For example, in an application, a lag might be caused by a heavy load on the slave. However, it can be difficult to generate this load level. Delayed replication can simulate the lag without having to simulate the load. It can also be used to debug conditions related to a lagging slave.
- To inspect what the database looked like in the past, without having to reload a backup. For example, by configuring a slave with a delay of one week, if you then need to see what the database looked like before the last few days' worth of development, the delayed slave can be inspected.

Replication Delay Timestamps

MySQL 8.0 provides a new method for measuring delay (also referred to as replication lag) in replication topologies that depends on the following timestamps associated with the GTID of each transaction (instead of each event) written to the binary log.

- `original_commit_timestamp`: the number of microseconds since epoch when the transaction was written (committed) to the binary log of the original master.
- `immediate_commit_timestamp`: the number of microseconds since epoch when the transaction was written (committed) to the binary log of the immediate master.

The output of `mysqlbinlog` displays these timestamps in two formats, microseconds from epoch and also `TIMESTAMP` format, which is based on the user defined time zone for better readability. For example:

```
#170404 10:48:05 server id 1  end_log_pos 233 CRC32 0x016ce647     GTID    last_committed=0
\ sequence_number=1    original_committed_timestamp=1491299285661130    immediate_commit_timestamp=1491
# original_commit_timestamp=1491299285661130 (2017-04-04 10:48:05.661130 WEST)
# immediate_commit_timestamp=1491299285843771 (2017-04-04 10:48:05.843771 WEST)
 /*!80001 SET @@SESSION.original_commit_timestamp=1491299285661130*//*!*/;
   SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa:1'/*!*/;
# at 233
```

As a rule, the `original_commit_timestamp` is always the same on all replicas where the transaction is applied. In master-slave replication, the `original_commit_timestamp` of a transaction in the (original) master's binary log is always the same as its `immediate_commit_timestamp`. In the slave's relay log, the `original_commit_timestamp` and `immediate_commit_timestamp` of the transaction are the same as in the master's binary log; whereas in its own binary log, the transaction's `immediate_commit_timestamp` corresponds to when the slave committed the transaction.

In a Group Replication setup, when the original master is a member of a group, the `original_commit_timestamp` is generated when the transaction is ready to be committed. In other words, when it finished executing on the original master and its write set is ready to be sent to all members of the group for certification. Therefore, the same `original_commit_timestamp` is replicated to all servers (regardless of whether it is a group member or slave replicating from a member) applying the transaction and each stores in its binary log the local commit time using `immediate_commit_timestamp`.

View change events, which are exclusive to Group Replication, are a special case. Transactions containing these events are generated by each server but share the same GTID (so, they are not first executed in a master and then replicated to the group, but all members of the group execute and apply the same transaction). Since there is no original master, these transactions have their `original_commit_timestamp` set to zero.

Monitoring Replication Delay

One of the most common ways to monitor replication delay (lag) in previous MySQL versions was by relying on the `Seconds_Behind_Master` field in the output of `SHOW SLAVE STATUS`. However, this metric is not suitable when using replication topologies more complex than the traditional master-slave setup, such as Group Replication. The addition of `immediate_commit_timestamp` and `original_commit_timestamp` to MySQL 8 provides a much finer degree of information about replication delay. The recommended method to monitor replication delay in a topology that supports these timestamps is using the following Performance Schema tables.

- `replication_connection_status`: current status of the connection to the master, provides information on the last and current transaction the connection thread queued into the relay log.
- `replication_applier_status_by_coordinator`: current status of the coordinator thread that only displays information when using a multithreaded slave, provides information on the last

transaction buffered by the coordinator thread to a worker's queue, as well as the transaction it is currently buffering.

- `replication_applier_status_by_worker`: current status of the thread(s) applying transactions received from the master, provides information about the transactions applied by the applier thread, or by each worker when using a multithreaded slave.

Using these tables you can monitor information about the last transaction the corresponding thread processed and the transaction that thread is currently processing. This information comprises:

- a transaction's GTID
- a transaction's `original_commit_timestamp` and `immediate_commit_timestamp`, retrieved from the slave's relay log
- the time a thread started processing a transaction
- for the last processed transaction, the time the thread finished processing it

In addition to the Performance Schema tables, the output of `SHOW SLAVE STATUS` has three fields that show:

- `SQL_Delay`: A nonnegative integer indicating the replication delay configured using `CHANGE MASTER TO MASTER_DELAY=N`, measured in seconds.
- `SQL_Remaining_Delay`: When `Slave_SQL_Running_State` is `Waiting until MASTER_DELAY seconds after master executed event`, this field contains an integer indicating the number of seconds left of the delay. At other times, this field is `NULL`.
- `Slave_SQL_Running_State`: A string indicating the state of the SQL thread (analogous to `Slave_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`.

When the slave SQL thread is waiting for the delay to elapse before executing an event, `SHOW PROCESSLIST` displays its `State` value as `Waiting until MASTER_DELAY seconds after master executed event`.

17.4 Replication Notes and Tips

17.4.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In other words, successful statement-based replication requires that any SQL features used be supported by both the master and the slave servers. If you use a feature on the master server that is available only in the current version of MySQL, you cannot replicate to a slave that uses an earlier version of MySQL. Such incompatibilities can also occur within a release series as well as between versions.

If you are planning to use statement-based replication between MySQL 8.0 and a previous MySQL release series, it is a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see Section 24.7, "Stored Program Binary Logging". For more information about row-based logging and row-based replication, see Section 5.4.4.1, "Binary Logging Formats", and Section 17.2.1, "Replication Formats".

For additional information specific to replication and InnoDB, see Section 15.18, “InnoDB and MySQL Replication”. For information relating to replication with NDB Cluster, see Section 22.6, “NDB Cluster Replication”.

17.4.1.1 Replication and AUTO_INCREMENT

Statement-based replication of AUTO_INCREMENT, LAST_INSERT_ID(), and TIMESTAMP values is carried out subject to the following exceptions:

- A statement invoking a trigger or function that causes an update to an AUTO_INCREMENT column is not replicated correctly using statement-based replication. These statements are marked as unsafe. (Bug #45677)
- An INSERT into a table that has a composite primary key that includes an AUTO_INCREMENT column that is not the first column of this composite key is not safe for statement-based logging or replication. These statements are marked as unsafe. (Bug #11754117, Bug #45670)

  This issue does not affect tables using the InnoDB storage engine, since an InnoDB table with an AUTO_INCREMENT column requires at least one key where the auto-increment column is the only or leftmost column.
- Adding an AUTO_INCREMENT column to a table with ALTER TABLE might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an AUTO_INCREMENT number. Assuming that you want to add an AUTO_INCREMENT column to a table t1 that has columns col1 and col2, the following statements produce a new table t2 identical to t1 but with an AUTO_INCREMENT column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

Important

To guarantee the same ordering on both master and slave, the ORDER BY clause must name *all* columns of t1.

The instructions just given are subject to the limitations of CREATE TABLE ... LIKE: Foreign key definitions are ignored, as are the DATA DIRECTORY and INDEX DIRECTORY table options. If a table definition includes any of those characteristics, create t2 using a CREATE TABLE statement that is identical to the one used to create t1, but with the addition of the AUTO_INCREMENT column.

Regardless of the method used to create and populate the copy having the AUTO_INCREMENT column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also Section B.6.6.1, “Problems with ALTER TABLE”.

17.4.1.2 Replication and BLACKHOLE Tables

The BLACKHOLE storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use. Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting BLACKHOLE tables are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped—they are not written to the binary log. A warning is logged whenever this occurs.

For this reason we recommend when you replicate to tables using the `BLACKHOLE` storage engine that you have the `binlog_format` server variable set to `STATEMENT`, and not to either `ROW` or `MIXED`.

17.4.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master has databases with a character set different from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

17.4.1.4 Replication and CHECKSUM TABLE

`CHECKSUM TABLE` returns a checksum that is calculated row by row, using a method that depends on the table row storage format. The storage format is not guaranteed to remain the same between MySQL versions, so the checksum value might change following an upgrade.

17.4.1.5 Replication of CREATE SERVER, ALTER SERVER, and DROP SERVER

The statements `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` are not written to the binary log, regardless of the binary logging format that is in use.

17.4.1.6 Replication of CREATE ... IF NOT EXISTS Statements

MySQL applies these rules when various `CREATE ... IF NOT EXISTS` statements are replicated:

- Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the master.
- Similarly, every `CREATE TABLE IF NOT EXISTS` statement without a `SELECT` is replicated, whether or not the table already exists on the master. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. Replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see Section 17.4.1.7, “Replication of CREATE TABLE ... SELECT Statements”, for more information.
- `CREATE EVENT IF NOT EXISTS` is always replicated, whether or not the event named in the statement already exists on the master.

17.4.1.7 Replication of CREATE TABLE ... SELECT Statements

MySQL applies these rules when `CREATE TABLE ... SELECT` statements are replicated:

- `CREATE TABLE ... SELECT` always performs an implicit commit (Section 13.3.3, “Statements That Cause an Implicit Commit”).
- If the destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.
  - `STATEMENT` or `MIXED` format: The statement is logged as written.
  - `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.
- If the `CREATE TABLE ... SELECT` statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.
- If the destination table exists and `IF NOT EXISTS` is given, MySQL 8.0 ignores the statement completely; nothing is inserted or logged.

When statement-based replication is in use, MySQL 8.0 does not allow a `CREATE TABLE ... SELECT` statement to make any changes in tables other than the table that is created by the statement. This is not an issue when using row-based replication, because the statement is logged as a `CREATE`

`TABLE` statement with any changes to table data logged as row-insert events, rather than as the entire `CREATE TABLE ... SELECT`.

17.4.1.8 Replication of CURRENT_USER()

The following statements support use of the `CURRENT_USER()` function to take the place of the name of, and possibly the host for, an affected user or a definer:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

When binary logging is enabled and `CURRENT_USER()` or `CURRENT_USER` is used as the definer in any of these statements, MySQL Server ensures that the statement is applied to the same user on both the master and the slave when the statement is replicated. In some cases, such as statements that change passwords, the function reference is expanded before it is written to the binary log, so that the statement includes the user name. For all other cases, the name of the current user on the master is replicated to the slave as metadata, and the slave applies the statement to the current user named in the metadata, rather than to the current user on the slave.

17.4.1.9 Replication with Differing Table Definitions on Master and Slave

Source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to certain conditions.

Note

Replication between tables which are partitioned differently from one another is not supported. See Section 17.4.1.24, “Replication and Partitioning”.

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the master and the slave. Additional conditions are discussed, with examples, in the following two sections.

Replication with More Columns on Master or Slave

You can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave.

  (This is true even if both tables have the same number of columns.)

- Columns common to both versions of the table must be defined before any additional columns.

  This means that executing an `ALTER TABLE` statement on the slave where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

  Suppose that a table `t`, existing on the master and the slave, is defined by the following `CREATE TABLE` statement:

  ```
  CREATE TABLE t (
      c1 INT,
      c2 INT,
      c3 INT
  );
  ```

  Suppose that the `ALTER TABLE` statement shown here is executed on the slave:

  ```
  ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
  ```

  The previous `ALTER TABLE` is permitted on the slave because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

  However, the following `ALTER TABLE` statement cannot be executed on the slave without causing replication to break:

  ```
  ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
  ```

  Replication fails after execution on the slave of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

  A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see Section 11.7, “Data Type Default Values”).

In addition, when the slave's copy of the table has more columns than the master's copy, each column common to the tables must use the same data type in both tables.

Examples. The following examples illustrate some valid and invalid table definitions:

More columns on the master. The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise an error because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave>  CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise an error because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT);
```

More columns on the slave. The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise an error because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave>  CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise an error because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave>  CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

```
master> CREATE TABLE t1 (c1 INT, c2 BIGINT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, this is not always strictly enforced, as long as certain conditions are met.

It is usually possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); when the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

Important

Whether you use statement-based or row-based replication, the slave's copy of the table cannot contain more columns than the master's copy if you wish to employ attribute promotion.

Statement-based replication. When using statement-based replication, a simple rule of thumb to follow is, “If the statement run on the master would also execute successfully on the slave, it should also replicate successfully”. In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave's copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

Row-based replication: attribute promotion and demotion. Row-based replication supports attribute promotion and demotion between smaller data types and larger types. It is also possible to

specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

Lossy and non-lossy conversions. In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a “fit” in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy* conversion.

Type conversion modes (slave_type_conversions variable). The setting of the `slave_type_conversions` global server variable controls the type conversion mode used on the slave. This variable takes a set of values from the following list, which describes the effects of each mode on the slave's type-conversion behavior:

ALL_LOSSY	In this mode, type conversions that would mean loss of information are permitted. This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling *only* this mode permits an `INT` column to be converted to `TINYINT` (a lossy conversion), but not a `TINYINT` column to an `INT` column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the slave.
ALL_NON_LOSSY	This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type. Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the `ALL_LOSSY` mode. If only `ALL_NON_LOSSY` is set, but not `ALL_LOSSY`, then attempting a conversion that would result in the loss of data (such as `INT` to `TINYINT`, or `CHAR(25)` to `VARCHAR(20)`) causes the slave to stop with an error.
ALL_LOSSY,ALL_NON_LOSSY	When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.
ALL_SIGNED	Treat promoted integer types as signed values (the default behavior).
ALL_UNSIGNED	Treat promoted integer types as unsigned values.
ALL_SIGNED,ALL_UNSIGNED	Treat promoted integer types as signed if possible, otherwise as unsigned.
[*empty*]	When `slave_type_conversions` is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types. This mode is the default.

When an integer type is promoted, its signedness is not preserved. By default, the slave treats all such values as signed. You can control this behavior using `ALL_SIGNED`, `ALL_UNSIGNED`, or both. `ALL_SIGNED` tells the slave to treat all promoted integer types as signed; `ALL_UNSIGNED` instructs it to treat these as unsigned. Specifying both causes the slave to treat the value as signed if possible, otherwise to treat it as unsigned; the order in which they are listed is not significant. Neither `ALL_SIGNED` nor `ALL_UNSIGNED` has any effect if at least one of `ALL_LOSSY` or `ALL_NONLOSSY` is not also used.

Changing the type conversion mode requires restarting the slave with the new `slave_type_conversions` setting.

Supported conversions. Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`.

  This includes conversions between the signed and unsigned versions of these types.

  Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For ensuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.

  `FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where `D' >= D` and `(M'-D') >= (M-D)` is non-lossy; for any case where `M' < M`, `D' < D`, or both, only a lossy conversion can be made.

  For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See Section 12.25.4, “Rounding Behavior”, for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.

  Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first `N` characters of the string on the slave, where `N` is the width of the target column.

  Important

  Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

  Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first `N` bytes of the string on the slave, where `N` is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

  When inserting a value from a `BIT(M)` column into a `BIT(M')` column, where `M' > M`, the most significant bits of the `BIT(M')` columns are cleared (set to zero) and the `M` bits of the `BIT(M)` value are set as the least significant bits of the `BIT(M')` column.

  When inserting a value from a source `BIT(M)` column into a target `BIT(M')` column, where `M' < M`, the maximum possible value for the `BIT(M')` column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

17.4.1.10 Replication and DIRECTORY Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the

slave server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the slave, which causes the slave to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see Section 5.1.11, “Server SQL Modes”.

17.4.1.11 Replication of DROP ... IF EXISTS Statements

The `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

`DROP ... IF EXISTS` statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master.

17.4.1.12 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See Section 12.2, “Type Conversion in Expression Evaluation”, and Section B.6.4.8, “Problems with Floating-Point Values”.

17.4.1.13 Replication and FLUSH

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a slave: `FLUSH LOGS` and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see Section 13.7.7.3, “FLUSH Syntax”. The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the slaves. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

17.4.1.14 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UUID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See Section 17.2.1, “Replication Formats”.)

  `USER()` and `CURRENT_USER()` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (See also Section 17.4.1.8, “Replication of CURRENT_USER()”.) This is also true for `VERSION()` and `RAND()`.

- For `NOW()`, the binary log includes the timestamp. This means that the value *as returned by the call to this function on the master* is replicated to the slave. To avoid unexpected results when replicating between MySQL servers in different time zones, set the time zone on both master and slave. See also Section 17.4.1.32, “Replication and Time Zones”

  To explain the potential problems when replicating between servers which are in different time zones, suppose that the master is located in New York, the slave is located in Stockholm, and both

servers are using local time. Suppose further that, on the master, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
+---------------------+
| 2009-09-01 12:00:00 |
+---------------------+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the slave at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the slave's copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the slave's copy of `mytable`, you obtain exactly the same result as on the master:

```
mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
+---------------------+
| 2009-09-01 12:00:00 |
+---------------------+
1 row in set (0.00 sec)
```

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the master and the slave to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the master and the slave.

`SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode.

See also Section 17.4.1.32, “Replication and Time Zones”.

- *The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES(GET_LOCK(...))`.

  These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode.

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

17.4.1.15 Replication and Fractional Seconds Support

MySQL 8.0 permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. See Section 11.3.5, “Fractional Seconds in Time Values”.

17.4.1.16 Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
  - `CREATE EVENT`
  - `ALTER EVENT`

- `DROP EVENT`
- `CREATE PROCEDURE`
- `DROP PROCEDURE`
- `CREATE FUNCTION`
- `DROP FUNCTION`
- `CREATE TRIGGER`
- `DROP TRIGGER`

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

Note

Attempting to replicate invoked features using statement-based replication produces the warning `Statement is not safe to log in statement format`. For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:
  - The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).
  - The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` store this information. See Section 25.10, "The INFORMATION_SCHEMA EVENTS Table", and Section 13.7.6.18, "SHOW EVENTS Syntax", for more information.
- The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), query the `INFORMATION_SCHEMA.EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
    FROM INFORMATION_SCHEMA.EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, you must enable each event using `ALTER EVENT event_name ENABLE`, where *`event_name`* is the name of the event.

If more than one master was involved in creating events on this slave, and you wish to identify events that were created only on a given master having the server ID *`master_id`*, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
```

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
    FROM INFORMATION_SCHEMA.EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED'
    AND   ORIGINATOR = 'master_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED'
    AND   ORIGINATOR = 'master_id'
```

Before enabling events that were replicated from the master, you should disable the MySQL Event Scheduler on the slave (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the slave afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`)-

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replication slave, you can identify the events by querying the `EVENTS` table, as shown here:

```
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
      FROM INFORMATION_SCHEMA.EVENTS
      WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

17.4.1.17 Replication of JSON Documents

Before MySQL 8.0, an update to a JSON column was always written to the binary log as the complete document. In MySQL 8.0, it is possible to log partial updates to JSON documents (see Partial Updates of JSON Values), which is more efficient. The logging behavior depends on the format used, as described here:

Statement-based replication. JSON partial updates are always logged as partial updates. This cannot be disabled when using statement-based logging.

Row-based replication. JSON partial updates are not logged as such by default, but instead are logged as complete documents. To enable logging of partial updates, set `binlog_row_value_options=PARTIAL_JSON`. If a replication master has this variable set, partial updates received from that master are handled and applied by a replication slave regardless of the slave's own setting for the variable.

Servers running MySQL 8.0.2 or earlier do not recognize the log events used for JSON partial updates. For this reason, when replicating to such a server from a server running MySQL 8.0.3 or later, `binlog_row_value_options` must be disabled on the master by setting this variable to `''` (empty string). See the description of this variable for more information.

17.4.1.18 Replication and LIMIT

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) When such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.

  When using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

17.4.1.19 Replication and LOAD DATA

`LOAD DATA` is considered unsafe for statement-based logging (see Section 17.2.1.3, "Determination of Safe and Unsafe Statements in Binary Logging"). When `binlog_format=MIXED` is set, the statement is logged in row-based format. When `binlog_format=STATEMENT` is set, note that `LOAD DATA` does not generate a warning, unlike other unsafe statements.

When `mysqlbinlog` reads log events for `LOAD DATA` statements logged in statement-based format, a generated local file is created in a temporary directory. These temporary files are not automatically removed by `mysqlbinlog` or any other MySQL program. If you do use `LOAD DATA` statements with statement-based binary logging, you should delete the temporary files yourself after you no longer need the statement log. For more information, see Section 4.6.8, "`mysqlbinlog` — Utility for Processing Binary Log Files".

17.4.1.20 Replication and max_allowed_packet

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If `max_allowed_packet` is too small on the slave, this also causes the slave to stop the I/O thread.

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

On a multi-threaded slave (with `slave_parallel_workers > 0`), ensure that the `slave_pending_jobs_size_max` system variable is set to a value equal to or greater than the setting for the `max_allowed_packet` system variable on the master. The default setting for `slave_pending_jobs_size_max`, 128M, is twice the default setting for `max_allowed_packet`, which is 64M. `max_allowed_packet` limits the packet size that the master will send, but the addition of an event header can produce a binary log event exceeding this size. Also, in row-based replication, a single event can be significantly larger than the `max_allowed_packet` size, because the value of `max_allowed_packet` only limits each column of the table.

The replication slave actually accepts packets up to the limit set by its `slave_max_allowed_packet` setting, which defaults to the maximum setting of 1GB, to prevent a replication failure due to a large packet. However, the value of `slave_pending_jobs_size_max` controls the memory that is made available on the slave to hold incoming packets. The specified memory is shared among all the slave worker queues.

The value of `slave_pending_jobs_size_max` is a soft limit, and if an unusually large event (consisting of one or multiple packets) exceeds this size, the transaction is held until all the slave workers have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed. So although unusual events larger than `slave_pending_jobs_size_max` can be processed, the delay to clear the queues of all the slave workers and the wait to queue subsequent transactions can cause lag on the replication slave and decreased concurrency of the slave workers. `slave_pending_jobs_size_max` should therefore be set high enough to accommodate most expected event sizes.

17.4.1.21 Replication and MEMORY Tables

When a master server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to slaves, the first time that the master uses a given `MEMORY` table after startup, it logs an event that notifies slaves that the table must to be emptied by writing a `DELETE` statement for that table to the binary log.

When a slave server shuts down and restarts, its `MEMORY` tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop:

- Row-format updates and deletes received from the master may fail with `Can't find record in 'memory_table'`.
- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the slave from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the slave again. This allows the slave to continue to replicate, but its `MEMORY` tables will still be different from those on the master. This can be okay if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

(The method just described is not applicable in NDB Cluster, where `slave_exec_mode` is always `IDEMPOTENT`, and cannot be changed.)

The size of `MEMORY` tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see Section 17.4.1.38, “Replication and Variables”). A change in `max_heap_table_size` takes effect for `MEMORY` tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY` or `TRUNCATE TABLE` following the change, or for all `MEMORY` tables following a server restart. If you increase the value of this variable on the master without doing so on the slave, it becomes possible for a table on the master to grow larger than its counterpart on the slave, leading to inserts that succeed on the master but fail on the slave with `Table is full` errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` on the slave as well as on the master, then restart replication. It is also recommended that you restart both the master and slave MySQL servers, to insure that the new value takes complete (global) effect on each of them.

See Section 16.3, “The MEMORY Storage Engine”, for more information about `MEMORY` tables.

17.4.1.22 Replication of the mysql System Schema

Data modification statements made to tables in the `mysql` schema are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

17.4.1.23 Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see Section 17.4.1.18, “Replication and LIMIT”, for a detailed discussion of these.

17.4.1.24 Replication and Partitioning

Replication is supported between partitioned tables as long as they use the same partitioning scheme and otherwise have the same structure except where an exception is specifically allowed (see Section 17.4.1.9, “Replication with Differing Table Definitions on Master and Slave”).

Replication between tables having different partitioning is generally not supported. This because statements (such as `ALTER TABLE ... DROP PARTITION`) acting directly on partitions in such

cases may produce different results on master and slave. In the case where a table is partitioned on the master but not on the slave, any statements operating on partitions on the master's copy of the slave fail on the slave. When the slave's copy of the table is partitioned but the master's copy is not, statements acting on partitions cannot be run on the master without causing errors there.

Due to these dangers of causing replication to fail entirely (on account of failed statements) and of inconsistencies (when the result of a partition-level SQL statement produces different results on master and slave), we recommend that insure that the partitioning of any tables to be replicated from the master is matched by the slave's versions of these tables.

17.4.1.25 Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

17.4.1.26 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. For example, a table column named `rank` on a MySQL 5.7 master that is replicating to a MySQL 8.0 slave could cause a problem because `RANK` is a reserved word beginning in MySQL 8.0.

Replication can fail in such cases with Error 1064 `You have an error in your SQL syntax...`, *even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication*. This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected. Only after the event is parsed can the slave apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (`` ` ``).

For listings of reserved words by MySQL version, see Reserved Words, in the *MySQL Server Version Reference*. For identifier quoting rules, see Section 9.2, “Schema Object Names”.

17.4.1.27 Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”.

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master

binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently. For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should also set `innodb_flush_log_at_trx_commit=1`. With this setting, the contents of the `InnoDB` redo log buffer are written out to the log file at each transaction commit and the log file is flushed to disk. Note that the durability of transactions is still not guaranteed with this setting, because operating systems or disk hardware may tell `mysqld` that the flush-to-disk operation has taken place, even though it has not.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see Section 17.4.1.30, “Replication and Temporary Tables”. Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates `relay-log.info`. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.
- A similar problem can occur if the slave updates `relay-log.info` but the server host crashes before the write has been flushed to disk. To minimize the chance of this occurring, set `sync_relay_log_info=1` in the slave `my.cnf` file. Setting `sync_relay_log_info` to 0 causes no writes to be forced to disk and the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

17.4.1.28 Slave Errors During Replication

If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

Note

If a temporary error is recorded in the slave's error log, you do not necessarily have to take any action suggested in the quoted error message. Temporary errors should be handled by the client retrying the transaction. For example, if the slave SQL thread records a temporary error relating to a deadlock, you do not need to restart the transaction manually on the slave, unless the slave SQL thread subsequently terminates with a nontemporary error message.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the

table, but not the other, or might cause an error for one version of the table, but not the other. For example, since `MyISAM` ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an `InnoDB` table on the master might cause a foreign key violation but the same statement performed on a `MyISAM` version of the same table on the slave would produce no such error, causing replication to stop.

17.4.1.29 Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same `INSERT` statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master's and slave's copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see Section 5.1.11, “Server SQL Modes”.

17.4.1.30 Replication and Temporary Tables

In MySQL 8.0, when `binlog_format` is set to `ROW` or `MIXED`, statements that exclusively use temporary tables are not logged on the master, and therefore the temporary tables are not replicated. Statements that involve a mix of temporary and nontemporary tables are logged on the master only for the operations on nontemporary tables, and the operations on temporary tables are not logged. This means that there are never any temporary tables on the slave to be lost in the event of an unplanned shutdown by the slave. For more information about row-based replication and temporary tables, see Row-based logging of temporary tables.

When `binlog_format` is set to `STATEMENT`, operations on temporary tables are logged on the master and replicated on the slave, provided that the statements involving temporary tables can be logged safely using statement-based format. In this situation, loss of replicated temporary tables on the slave can be an issue. In statement-based replication mode, `CREATE TEMPORARY TABLE` and `DROP TEMPORARY TABLE` statements cannot be used inside a transaction, procedure, function, or trigger when GTIDs are in use on the server (that is, when the `enforce_gtid_consistency` system variable is set to `ON`). They can be used outside these contexts when GTIDs are in use, provided that `autocommit=1` is set.

Because of the differences in behavior between row-based or mixed replication mode and statement-based replication mode regarding temporary tables, you cannot switch the replication format at runtime, if the change applies to a context (global or session) that contains any open temporary tables. For more details, see the description of the `binlog_format` option.

Safe slave shutdown when using temporary tables. In statement-based replication mode, temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.
3. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD` and repeat the procedure later.
4. When the value is 0, issue a `mysqladmin shutdown` command to stop the slave.

Temporary tables and replication options. By default, with statement-based replication, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables. The exception is that to enable correct removal of temporary tables at the end of a session, a replication slave always replicates a `DROP TEMPORARY TABLE IF EXISTS` statement, regardless of any exclusion rules that would normally apply for the specified table.

A recommended practice when using statement-based replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent them from being replicated.

17.4.1.31 Replication Retries and Timeouts

The global system variable `slave_transaction_retries` sets the maximum number of times for applier threads on a single-threaded or multithreaded replication slave to automatically retry failed transactions before stopping. Transactions are automatically retried when the SQL thread fails to execute them because of an `InnoDB` deadlock, or when the transaction's execution time exceeds the `InnoDB` `innodb_lock_wait_timeout` value. If a transaction has a non-temporary error that will prevent it from ever succeeding, it is not retried.

The default setting for `slave_transaction_retries` is 10, meaning that a failing transaction with an apparently temporary error is retried 10 times before the applier thread stops. Setting the variable to 0 disables automatic retrying of transactions. On a multithreaded slave, the specified number of transaction retries can take place on all applier threads of all channels. The Performance Schema table `replication_applier_status` shows the total number of transaction retries that took place on each replication channel, in the `COUNT_TRANSACTIONS_RETRIES` column.

The process of retrying transactions can cause lag on a replication slave or on a Group Replication group member, which can be configured as a single-threaded or multithreaded slave. The Performance Schema table `replication_applier_status_by_worker` shows detailed information on transaction retries by the applier threads on a single-threaded or multithreaded slave. This data includes timestamps showing how long it took the applier thread to apply the last transaction from start to finish (and when the transaction currently in progress was started), and how long this was after the commit on the original master and the immediate master. The data also shows the number of retries for the last transaction and the transaction currently in progress, and enables you to identify the transient errors that caused the transactions to be retried. You can use this information to see whether transaction retries are the cause of replication lag, and investigate the root cause of the failures that led to the retries.

17.4.1.32 Replication and Time Zones

By default, master and slave servers assume that they are in the same time zone. If you are replicating between servers in different time zones, the time zone must be set on both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. Set the time zone in which MySQL server runs by using the `--timezone=`*`timezone_name`* option of the `mysqld_safe` script or by setting the `TZ` environment variable. See also Section 17.4.1.14, “Replication and System Functions”.

17.4.1.33 Replication and Transaction Inconsistencies

Inconsistencies in the sequence of transactions that have been executed from the relay log can occur depending on your replication configuration. This section explains how to avoid inconsistencies and solve any problems they cause.

The following types of inconsistencies can exist:

- *Half-applied transactions*. A transaction which updates non-transactional tables has applied some but not all of its changes.
- *Gaps*. A gap is a transaction that has not been (fully) applied, even though some later transaction has been applied. Gaps can only appear when using a multithreaded slave. To avoid gaps occurring, set `slave_preserve_commit_order=1`, which requires `slave_parallel_type=LOGICAL_CLOCK`, and that binary logging (the `log_bin` system variable) and slave update logging (the `--log-slave-updates`) are also enabled.
- *Gap-free low-watermark position*. Even in the absence of gaps, it is possible that transactions after `Exec_master_log_pos` have been applied. That is, all transactions up to point `N` have been applied, and no transactions after `N` have been applied, but `Exec_master_log_pos` has a value smaller than `N.` This can only happen on multithreaded slaves. Enabling `slave_preserve_commit_order` does *not* prevent gap-free low-watermark positions.

The following scenarios are relevant to the existence of half-applied transactions, gaps, and gap-free low-watermark position inconsistencies:

1. While slave threads are running, there may be gaps and half-applied transactions.
2. `mysqld` shuts down. Both clean and unclean shutdown abort ongoing transactions and may leave gaps and half-applied transactions.
3. `KILL` of replication threads (the SQL thread when using a single-threaded slave, the coordinator thread when using a multithreaded slave). This aborts ongoing transactions and may leave gaps and half-applied transactions.
4. Error in applier threads. This may leave gaps. If the error is in a mixed transaction, that transaction is half-applied. When using a multithreaded slave, workers which have not received an error complete their queues, so it may take time to stop all threads.
5. `STOP SLAVE` when using a multithreaded slave. After issuing `STOP SLAVE`, the slave waits for any gaps to be filled and then updates `Exec_master_log_pos`. This ensures it never leaves gaps or gap-free low-watermark positions, unless any of the cases above applies (in other words, before `STOP SLAVE` completes, either an error happens, or another thread issues `KILL`, or the server restarts. In these cases, `STOP SLAVE` returns successfully.)
6. If the last transaction in the relay log is only half-received and the multithreaded slave coordinator has started to schedule the transaction to a worker, then `STOP SLAVE` waits up to 60 seconds for the transaction to be received. After this timeout, the coordinator gives up and aborts the transaction. If the transaction is mixed, it may be left half-completed.
7. `STOP SLAVE` when using a single-threaded slave. If the ongoing transaction only updates transactional tables, it is rolled back and `STOP SLAVE` stops immediately. If the ongoing transaction is mixed, `STOP SLAVE` waits up to 60 seconds for the transaction to complete. After this timeout, it aborts the transaction, so it may be left half-completed.

The global variable `rpl_stop_slave_timeout` is unrelated to the process of stopping the replication threads. It only makes the client that issues `STOP SLAVE` return to the client, but the replication threads continue to try to stop.

If a replication channel has gaps, it has the following consequences:

1. The slave database is in a state that may never have existed on the master.
2. The field `Exec_master_log_pos` in `SHOW SLAVE STATUS` is only a "low-watermark". In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not.
3. `CHANGE MASTER TO` statements for that channel fail with an error, unless the applier threads are running and the `CHANGE MASTER TO` statement only sets receiver options.

4. If `mysqld` is started with `--relay-log-recovery`, no recovery is done for that channel, and a warning is printed.

5. If `mysqldump` is used with `--dump-slave`, it does not record the existence of gaps; thus it prints `CHANGE MASTER TO` with `RELAY_LOG_POS` set to the low-watermark position in `Exec_master_log_pos`.

   After applying the dump on another server, and starting the replication threads, transactions appearing after the position are replicated again. Note that this is harmless if GTIDs are enabled (however, in that case it is not recommended to use `--dump-slave`).

If a replication channel has a gap-free low-watermark position, cases 2 to 5 above apply, but case 1 does not.

The gap-free low-watermark position information is persisted in binary format in the internal table `mysql.slave_worker_info`. `START SLAVE [SQL_THREAD]` always consults this information so that it applies only the correct transactions. This remains true even if `slave_parallel_workers` has been changed to 0 before `START SLAVE`, and even if `START SLAVE` is used with `UNTIL` clauses. `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` only applies as many transactions as needed in order to fill in the gaps. If `START SLAVE` is used with `UNTIL` clauses that tell it to stop before it has consumed all the gaps, then it leaves remaining gaps.

Warning

`RESET SLAVE` removes the relay logs and resets the replication position. Thus issuing `RESET SLAVE` on a slave with gaps means the slave loses any information about the gaps, without correcting the gaps.

`slave-preserve-commit-order` ensures that there are no gaps. However, it is still possible that `Exec_master_log_pos` is just a gap-free low-watermark position in scenarios 1 to 4 above. That is, there may be transactions after `Exec_master_log_pos` which have been applied. Therefore the cases numbered 2 to 5 above (but not case 1) apply, even when `slave-preserve-commit-order` is enabled.

17.4.1.34 Replication and Transactions

Mixing transactional and nontransactional statements within the same transaction. In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

The server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)

- For statement-based logging, logging of nontransactional statements is affected by the `binlog_direct_non_transactional_updates` system variable. When this variable is `OFF` (the default), logging is as just described. When this variable is `ON`, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog_direct_non_transactional_updates` has no effect for row-format or mixed-format binary logging.

Transactional, nontransactional, and mixed statements.
To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. A statement that references both nontransactional and transactional tables and updates *any* of the tables involved is

considered a “mixed” statement. Mixed statements, like transactional statements, are cached and logged when the transaction commits.

A mixed statement that updates a transactional table is considered unsafe if the statement also performs either of the following actions:

- Updates or reads a temporary table
- Reads a nontransactional table and the transaction isolation level is less than REPEATABLE_READ

A mixed statement following the update of a transactional table within a transaction is considered unsafe if it performs either of the following actions:

- Updates any table and reads from any temporary table
- Updates a nontransactional table and `binlog_direct_non_transactional_updates` is OFF

For more information, see Section 17.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”.

Note

A mixed statement is unrelated to mixed binary logging format.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

Using different storage engines on master and slave. It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an `InnoDB` master table as a `MyISAM` slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN` ... `COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

It is also safe to replicate transactions from `MyISAM` tables on the master to transactional tables—such as tables that use the `InnoDB` storage engine—on the slave. In such cases, an `AUTOCOMMIT=1` statement issued on the master is replicated, thus enforcing `AUTOCOMMIT` mode on the slave.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

Changing the binary logging format within transactions. The `binlog_format` and `binlog_checksum` system variables are read-only as long as a transaction is in progress.

Every transaction (including `autocommit` transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. This is even true for statements affecting tables that use a nontransactional storage engine (such as `MyISAM`).

Note

For restrictions that apply specifically to XA transactions, see Section C.6, “Restrictions on XA Transactions”.

17.4.1.35 Replication and Triggers

With statement-based replication, triggers executed on the master also execute on the slave. With row-based replication, triggers executed on the master do not execute on the slave. Instead, the row changes on the master resulting from trigger execution are replicated and applied on the slave.

This behavior is by design. If under row-based replication the slave applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—you must use statement-based replication. However, to enable slave-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

A statement invoking a trigger (or function) that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. MySQL 8.0 marks such statements as unsafe. (Bug #45677)

A trigger can have triggers for different combinations of trigger event (`INSERT`, `UPDATE`, `DELETE`) and action time (`BEFORE`, `AFTER`), and multiple triggers are permitted.

For brevity, “multiple triggers” here is shorthand for “multiple triggers that have the same trigger event and action time.”

Upgrades. Multiple triggers are not supported in versions earlier than MySQL 5.7. If you upgrade servers in a replication topology that use a version earlier than MySQL 5.7, upgrade the replication slaves first and then upgrade the master. If an upgraded replication master still has old slaves using MySQL versions that do not support multiple triggers, an error occurs on those slaves if a trigger is created on the master for a table that already has a trigger with the same trigger event and action time.

Downgrades. If you downgrade a server that supports multiple triggers to an older version that does not, the downgrade has these effects:

- For each table that has triggers, all trigger definitions are in the `.TRG` file for the table. However, if there are multiple triggers with the same trigger event and action time, the server executes only one of them when the trigger event occurs. For information about `.TRG` files, see the Table Trigger Storage section of the MySQL Server Doxygen documentation, available at https://dev.mysql.com/doc/index-other.html.
- If triggers for the table are added or dropped subsequent to the downgrade, the server rewrites the table's `.TRG` file. The rewritten file retains only one trigger per combination of trigger event and action time; the others are lost.

To avoid these problems, modify your triggers before downgrading. For each table that has multiple triggers per combination of trigger event and action time, convert each such set of triggers to a single trigger as follows:

1. For each trigger, create a stored routine that contains all the code in the trigger. Values accessed using `NEW` and `OLD` can be passed to the routine using parameters. If the trigger needs a single result value from the code, you can put the code in a stored function and have the function return the value. If the trigger needs multiple result values from the code, you can put the code in a stored procedure and return the values using `OUT` parameters.
2. Drop all triggers for the table.
3. Create one new trigger for the table that invokes the stored routines just created. The effect for this trigger is thus the same as the multiple triggers it replaces.

17.4.1.36 Replication and TRUNCATE TABLE

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`.

However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

`TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replication slaves still follow the rules described in Section 13.1.37, “TRUNCATE TABLE Syntax” governing such tables. (Bug #36763)

17.4.1.37 Replication and User Name Length

The maximum length of MySQL user names is 32 characters. Replication of user names longer than 16 characters to a slave earlier than MySQL 5.7 that supports only shorter user names will fail. However, this should occur only when replicating from a newer master to an older slave, which is not a recommended configuration.

17.4.1.38 Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

When `MIXED` mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See Section 5.4.4.3, “Mixed Binary Logging Format”.

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the slave always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the master. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = mode` statement, the full *`mode`* value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when `STATEMENT` mode is in use.

The `default_storage_engine` system variable is not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

The `max_heap_table_size` system variable is not replicated. Increasing the value of this variable on the master without doing so on the slave can lead eventually to `Table is full` errors on the slave when trying to execute `INSERT` statements on a `MEMORY` table on the master that is thus permitted to grow larger than its counterpart on the slave. For more information, see Section 17.4.1.21, “Replication and MEMORY Tables”.

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See Section 17.2.1, “Replication Formats”.

The following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

Important

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

To help reduce possible confusion, we recommend that you always use the same setting for the `lower_case_table_names` system variable on both master and slave, especially when you are running MySQL on platforms with case-sensitive file systems. The `lower_case_table_names` setting can only be configured when initializing the server.

17.4.1.39 Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a same-named view is supported using statement-based logging, but not when using row-based logging. Trying to do so when row-based logging is in effect causes an error.

17.4.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from one release series to the next higher release series. For example, you can replicate from a master running MySQL 5.6 to a slave running MySQL 5.7, from a master running MySQL 5.7 to a slave running MySQL 8.0, and so on. However, you might encounter difficulties when replicating from an older master to a newer slave if the master uses statements or relies on behavior no longer supported in the version of MySQL used on the slave. For example, foreign key names longer than 64 characters are no longer supported from MySQL 8.0.

The use of more than two MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to release series, but to version numbers within the same release series as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 8.0.1, MySQL 8.0.2, and MySQL 8.0.4 concurrently, although you could use any two of these releases together.

Important

It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

From MySQL 8.0.14, the server version is recorded in the binary log for each transaction for the server that originally committed the transaction (`original_server_version`), and for the server that is the immediate master of the current server in the replication topology (`immediate_server_version`).

Replication from newer masters to older slaves might be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible.

  This also has significant implications for upgrading replication servers; see Section 17.4.3, “Upgrading a Replication Setup”, for more information.

- For more information about row-based replication, see Section 17.2.1, “Replication Formats”.

- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

  However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

For more information on potential replication issues, see Section 17.4.1, “Replication Features and Issues”.

17.4.3 Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading. This section provides information about how upgrading affects replication. For general information about upgrading MySQL, see Section 2.11, “Upgrading MySQL”

When you upgrade a master to 8.0 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 8.0.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 8.0.x version, restart it, and restart replication. Relay logs created by the slave after the upgrade are in 8.0 format.

Changes affecting operations in strict SQL mode (`STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES`) may result in replication failure on an upgraded slave. If you use statement-based logging (`binlog_format=STATEMENT`), if a slave is upgraded before the master, the nonupgraded master will execute statements without error that may fail on the slave and replication will stop. To deal with this, stop all new statements on the master and wait until the slaves catch up. Then upgrade the slaves. Alternatively, if you cannot stop new statements, temporarily change to row-based logging on the master (`binlog_format=ROW`) and wait until all slaves have processed all binary logs produced up to the point of this change. Then upgrade the slaves.

The default character set has changed from `latin1` to `utf8mb4` in MySQL 8.0. In a replicated setting, when upgrading from MySQL 5.7 to 8.0, it is advisable to change the default character set back to the character set used in MySQL 5.7 before upgrading. After the upgrade is completed, the default character set can be changed to `utf8mb4`. Assuming that the previous defaults were used, one way to preserve them is to start the server with these lines in the `my.cnf` file:

```
[mysqld]
character_set_server=latin1
collation_server=latin1_swedish_ci
```

After the slaves have been upgraded, shut down the master, upgrade it to the same 8.0.x release as the slaves, and restart it. If you had temporarily changed the master to row-based logging, change it back to statement-based logging. The 8.0 master is able to read the old binary logs written prior to the upgrade and to send them to the 8.0 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 8.0 format. These too are recognized by the 8.0 slaves.

In other words, when upgrading to MySQL 8.0, the slaves must be MySQL 8.0 before you can upgrade the master to 8.0. Note that downgrading from 8.0 to older versions does not work so simply: You must ensure that any 8.0 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, are detailed at Section 2.11.4, “Changes in MySQL 8.0”. It is safest to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the `--skip-slave-start` option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of `REPAIR TABLE` or `ALTER TABLE`, or dumping and reloading tables or triggers.

2. Disable the binary log on the master. To do this without restarting the master, execute a `SET sql_log_bin = OFF` statement. Alternatively, stop the master and restart it with the `--skip-log-bin` option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the `--skip-networking` option when you restart the master.

3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.

4. Re-enable the binary log on the master. If you set `sql_log_bin` to `OFF` earlier, execute a `SET sql_log_bin = ON` statement. If you restarted the master to disable the binary log, restart it without `--skip-log-bin`, and without `--skip-networking` so that clients and slaves can connect.

5. Restart the slaves, this time without the `--skip-slave-start` option.

If you are upgrading an existing replication setup from a version of MySQL that does not support global transaction identifiers to a version that does, you should not enable GTIDs on either the master or the slave before making sure that the setup meets all the requirements for GTID-based replication. See Section 17.1.3.4, “Setting Up Replication Using GTIDs”, which contains information about converting existing replication setups to use GTID-based replication.

Prior to MySQL 8.0.16, when the server is running with global transaction identifiers (GTIDs) enabled (`gtid_mode=ON`), do not enable binary logging by `mysql_upgrade` (the `--write-binlog` option). As of MySQL 8.0.16, the server performs the entire MySQL upgrade procedure, but disables binary logging during the upgrade, so there is no issue.

It is not recommended to load a dump file when GTIDs are enabled on the server (`gtid_mode=ON`), if your dump file includes system tables. `mysqldump` issues DML instructions for the system tables which use the non-transactional MyISAM storage engine, and this combination is not permitted when GTIDs are enabled. Also be aware that loading a dump file from a server with GTIDs enabled, into another server with GTIDs enabled, causes different transaction identifiers to be generated.

17.4.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. Binary logging is enabled by default. If binary logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are not running the master with any settings that disable binary logging, such as the `--skip-log-bin` option.

- Verify that the master and slave both were started with the `--server-id` option and that the ID value is unique on each server.

- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.

- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See Section 17.2.2, “Replication Implementation Details”. If the I/O thread state says `Connecting to master`, check the following:

  - Verify the privileges for the user being used for replication on the master.

  - Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.

  - Check that networking has not been disabled on the master or slave. Look for the `skip-networking` option in the configuration file. If present, comment it out or remove it.
  - If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
  - Check that you can reach the master by using `ping` or `traceroute`/`tracert` to reach the host.

- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in Section 17.4.1, “Replication Features and Issues”. If it is a bug, see Section 17.4.5, “How to Report Replication Bugs or Problems”, for instructions on how to report it.

- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:

  1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.
  2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
  3. If you decide that the slave can skip the next statement from the master, issue the following statements:

     ```
     mysql> SET GLOBAL sql_slave_skip_counter = N;
     mysql> START SLAVE;
     ```

     The value of *`N`* should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

     See also Section 13.4.2.5, “SET GLOBAL sql_slave_skip_counter Syntax”.
  4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

17.4.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”. If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In

this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*

2. Ensure that the slave is running with binary logging enabled (the `log_bin` system variable), and with the `--log-slave-updates` option enabled, which causes the slave to log the updates that it receives from the master into its own binary logs. These settings are the defaults.

3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:

   - All binary log files from the master
   - All binary log files from the slave
   - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
   - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
   - Error logs from the master and the slave

4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. *`log_file`* and *`log_pos`* are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

   ```
   shell> mysqlbinlog --start-position=log_pos log_file | head
   ```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at Section 1.7, “How to Report Bugs or Problems”.

Chapter 18 Group Replication

Table of Contents

18.1 Group Replication Background 3080
18.1.1 Replication Technologies 3081
18.1.2 Group Replication Use Cases 3082

18.11.6 Observability 3183

This chapter explains MySQL Group Replication and how to install, configure and monitor groups. MySQL Group Replication is a MySQL Server plugin that enables you to create elastic, highly-available, fault-tolerant replication topologies.

Groups can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users, groups can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

The chapter is structured as follows:

- Section 18.1, “Group Replication Background” provides an introduction to groups and how Group Replication works.
- Section 18.2, “Getting Started” explains how to configure multiple MySQL Server instances to create a group.
- Section 18.3, “Monitoring Group Replication” explains how to monitor a group.
- Section 18.4, “Group Replication Operations” explains how to work with a group.
- Section 18.5, “Group Replication Security” explains how to secure a group.
- Section 18.7, “Upgrading Group Replication” explains how to upgrade a group.
- Section 18.11, “Group Replication Technical Details” provides in-depth information about how Group Replication works.

18.1 Group Replication Background

This section provides background information on MySQL Group Replication.

The most common way to create a fault-tolerant system is to resort to making components redundant, in other words the component can be removed and the system should continue to operate as expected. This creates a set of challenges that raise complexity of such systems to a whole different level. Specifically, replicated databases have to deal with the fact that they require maintenance and administration of several servers instead of just one. Moreover, as servers are cooperating together to create the group several other classic distributed systems problems have to be dealt with, such as network partitioning or split brain scenarios.

Therefore, the ultimate challenge is to fuse the logic of the database and data replication with the logic of having several servers coordinated in a consistent and simple way. In other words, to have multiple servers agreeing on the state of the system and the data on each and every change that the system goes through. This can be summarized as having servers reaching agreement on each database state transition, so that they all progress as one single database or alternatively that they eventually converge to the same state. Meaning that they need to operate as a (distributed) state machine.

MySQL Group Replication provides distributed state machine replication with strong coordination between servers. Servers coordinate themselves automatically when they are part of the same group. The group can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users the group can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently. This power comes at the expense of applications having to work around the limitations imposed by such deployments.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

For a transaction to commit, the majority of the group have to agree on the order of a given transaction in the global sequence of transactions. Deciding to commit or abort a transaction is done by each server individually, but all servers make the same decision. If there is a network partition, resulting in a split where members are unable to reach agreement, then the system does not progress until this issue is resolved. Hence there is also a built-in, automatic, split-brain protection mechanism.

All of this is powered by the provided Group Communication System (GCS) protocols. These provide a failure detection mechanism, a group membership service, and safe and completely ordered message delivery. All these properties are key to creating a system which ensures that data is consistently replicated across the group of servers. At the very core of this technology lies an implementation of the Paxos algorithm. It acts as the group communication engine.

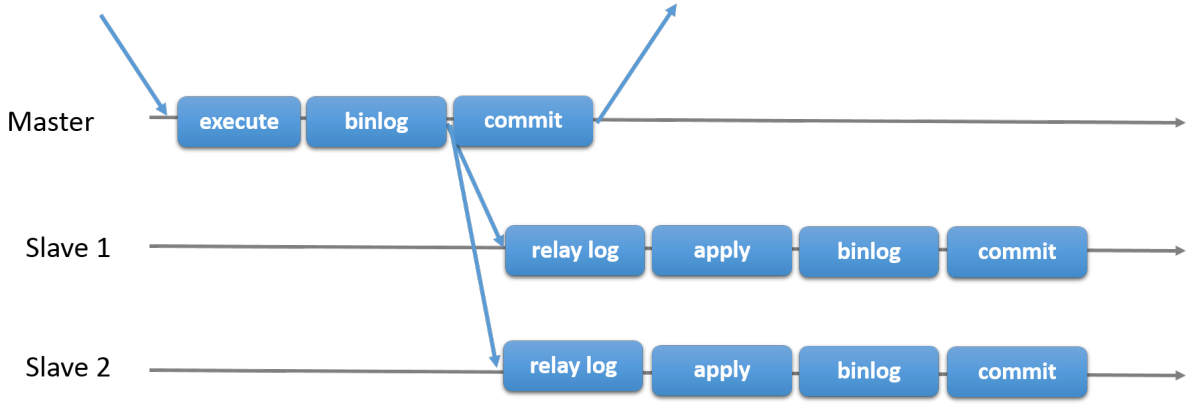
18.1.1 Replication Technologies

Before getting into the details of MySQL Group Replication, this section introduces some background concepts and an overview of how things work. This provides some context to help understand what is required for Group Replication and what the differences are between classic asynchronous MySQL Replication and Group Replication.

18.1.1.1 Primary-Secondary Replication

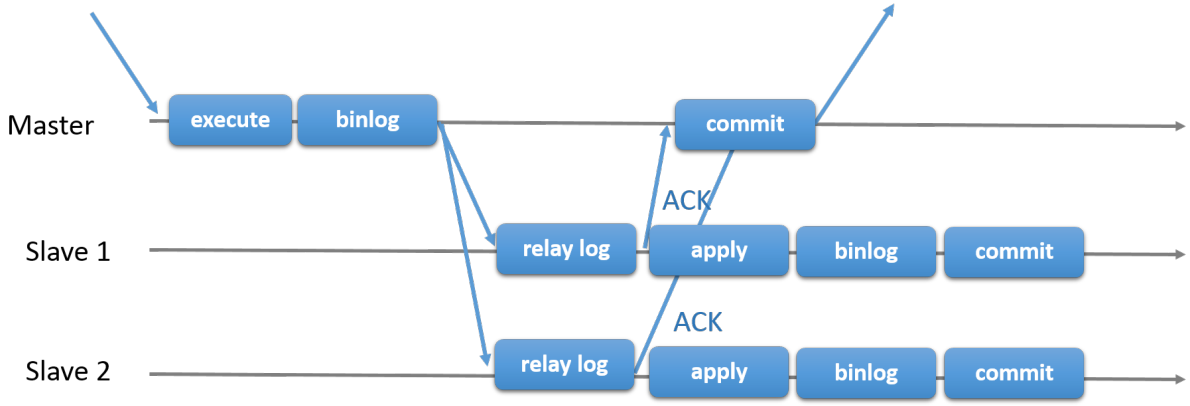
Traditional MySQL Replication provides a simple Primary-Secondary approach to replication. There is a primary (master) and there is one or more secondaries (slaves). The primary executes transactions, commits them and then they are later (thus asynchronously) sent to the secondaries to be either re-executed (in statement-based replication) or applied (in row-based replication). It is a shared-nothing system, where all servers have a full copy of the data by default.

Figure 18.1 MySQL Asynchronous Replication



There is also semisynchronous replication, which adds one synchronization step to the protocol. This means that the Primary waits, at commit time, for the secondary to acknowledge that it has *received* the transaction. Only then does the Primary resume the commit operation.

Figure 18.2 MySQL Semisynchronous Replication



In the two pictures above, you can see a diagram of the classic asynchronous MySQL Replication protocol (and its semisynchronous variant as well). Diagonal arrows represent messages exchanged between servers or messages exchanged between servers and the client application.

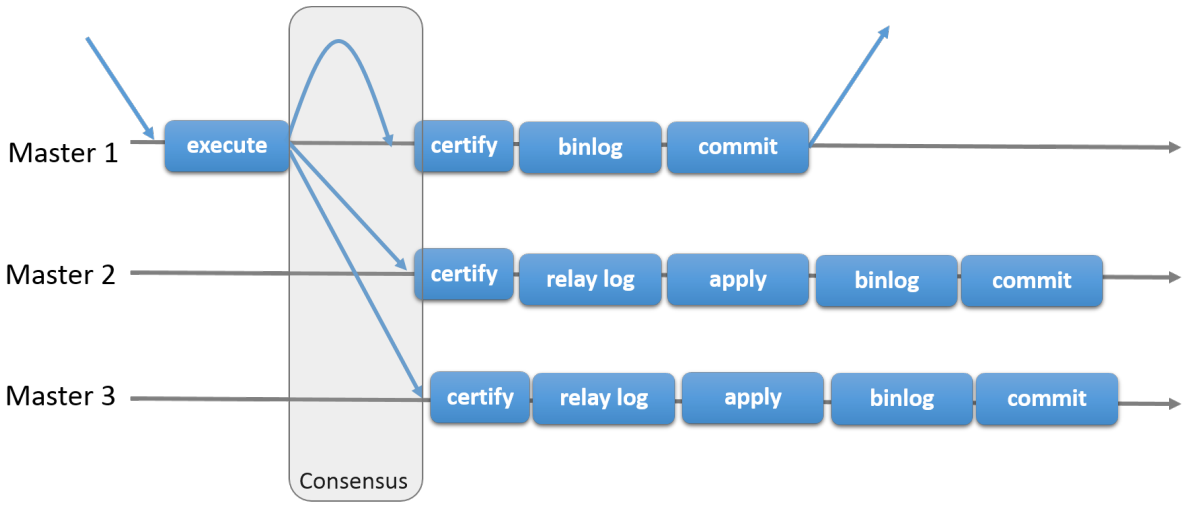
18.1.1.2 Group Replication

Group Replication is a technique that can be used to implement fault-tolerant systems. The replication group is a set of servers that interact with each other through message passing. The communication layer provides a set of guarantees such as atomic message and total order message delivery. These are very powerful properties that translate into very useful abstractions that one can resort to build more advanced database replication solutions.

MySQL Group Replication builds on top of such properties and abstractions and implements a multi-master update everywhere replication protocol. In essence, a replication group is formed by multiple servers and each server in the group may execute transactions independently. But all read-write (RW) transactions commit only after they have been approved by the group. Read-only (RO) transactions need no coordination within the group and thus commit immediately. In other words, for any RW transaction the group needs to decide whether it commits or not, thus the commit operation is not a unilateral decision from the originating server. To be precise, when a transaction is ready to commit at the originating server, the server atomically broadcasts the write values (rows changed) and the correspondent write set (unique identifiers of the rows that were updated). Then a global total order is established for that transaction. Ultimately, this means that all servers receive the same set of transactions in the same order. As a consequence, all servers apply the same set of changes in the same order, therefore they remain consistent within the group.

However, there may be conflicts between transactions that execute concurrently on different servers. Such conflicts are detected by inspecting the write sets of two different and concurrent transactions, in a process called *certification*. If two concurrent transactions, that executed on different servers, update the same row, then there is a conflict. The resolution procedure states that the transaction that was ordered first commits on all servers, whereas the transaction ordered second aborts, and thus is rolled back on the originating server and dropped by the other servers in the group. This is in fact a distributed first commit wins rule.

Figure 18.3 MySQL Group Replication Protocol



Finally, Group Replication is a shared-nothing replication scheme where each server has its own entire copy of the data.

The figure above depicts the MySQL Group Replication protocol and by comparing it to MySQL Replication (or even MySQL semisynchronous replication) you can see some differences. Note that some underlying consensus and Paxos related messages are missing from this picture for the sake of clarity.

18.1.2 Group Replication Use Cases

Group Replication enables you to create fault-tolerant systems with redundancy by replicating the system state to a set of servers. Even if some of the servers subsequently fail, as long it is not all

or a majority, the system is still available. Depending on the number of servers which fail the group might have degraded performance or scalability, but it is still available. Server failures are isolated and independent. They are tracked by a group membership service which relies on a distributed failure detector that is able to signal when any servers leave the group, either voluntarily or due to an unexpected halt. There is a distributed recovery procedure to ensure that when servers join the group they are brought up to date automatically. There is no need for server fail-over, and the multi-master update everywhere nature ensures that even updates are not blocked in the event of a single server failure. To summarize, MySQL Group Replication guarantees that the database service is continuously available.

It is important to understand that although the database service is available, in the event of a server crash, those clients connected to it must be redirected, or failed over, to a different server. This is not something Group Replication attempts to resolve. A connector, load balancer, router, or some form of middleware are more suitable to deal with this issue. For example see MySQL Router 8.0.

To summarize, MySQL Group Replication provides a highly available, highly elastic, dependable MySQL service.

18.1.2.1 Examples of Use Case Scenarios

The following examples are typical use cases for Group Replication.

- *Elastic Replication* - Environments that require a very fluid replication infrastructure, where the number of servers has to grow or shrink dynamically and with as few side-effects as possible. For instance, database services for the cloud.
- *Highly Available Shards* - Sharding is a popular approach to achieve write scale-out. Use MySQL Group Replication to implement highly available shards, where each shard maps to a replication group.
- *Alternative to Master-Slave replication* - In certain situations, using a single master server makes it a single point of contention. Writing to an entire group may prove more scalable under certain circumstances.
- *Autonomic Systems* - Additionally, you can deploy MySQL Group Replication purely for the automation that is built into the replication protocol (described already in this and previous chapters).

18.1.3 Group Replication Details

This section presents details about some of the services that Group Replication builds on.

18.1.3.1 Failure Detection

Group Replication includes a failure detection mechanism that is able to find and report which servers are silent and as such assumed to be dead. At a high level, the failure detector is a distributed service that provides information about which servers may be dead (suspicions). Suspicions are triggered when servers go mute. When server A does not receive messages from server B during a given period, a timeout occurs and a suspicion is raised. Later if the group agrees that the suspicions are probably true, then the group decides that a given server has indeed failed. This means that the remaining members in the group take a coordinated decision to exclude a given member.

If a server gets isolated from the rest of the group, then it suspects that all others have failed. Being unable to secure agreement with the group (as it cannot secure a quorum), its suspicion does not have consequences. When a server is isolated from the group in this way, it is unable to execute any local transactions.

For information on the Group Replication system variables that you can configure to specify the responses of working group members, and group members that are suspected of having failed, to these situations, see Section 18.6.6, “Responses to Failure Detection and Network Partitioning”.

18.1.3.2 Group Membership

MySQL Group Replication relies on a group membership service. This is built into the plugin. It defines which servers are online and participating in the group. The list of online servers is often referred to as a *view*. Therefore, every server in the group has a consistent view of which are the members participating actively in the group at a given moment in time.

Servers have to agree not only on transaction commits, but also which is the current view. Therefore, if servers agree that a new server becomes part of the group, then the group itself is reconfigured to integrate that server in it, triggering a view change. The opposite also happens, if a server leaves the group, voluntarily or not, then the group dynamically rearranges its configuration and a view change is triggered.

Note though that when a member leaves voluntarily, it first initiates a dynamic group reconfiguration. This triggers a procedure, where all members have to agree on the new view without the leaving server. However, if a member leaves involuntarily (for example it has stopped unexpectedly or the network connection is down) then the failure detection mechanism realizes this fact and a reconfiguration of the group is proposed, this one without the failed member. As mentioned this requires agreement from the majority of servers in the group. If the group is not able to reach agreement (for example it partitioned in such a way that there is no majority of servers online), then the system is not be able to dynamically change the configuration and as such, blocks to prevent a split-brain situation. Ultimately, this means that the administrator needs to step in and fix this.

18.1.3.3 Fault-tolerance

MySQL Group Replication builds on an implementation of the Paxos distributed algorithm to provide distributed coordination between servers. As such, it requires a majority of servers to be active to reach quorum and thus make a decision. This has direct impact on the number of failures the system can tolerate without compromising itself and its overall functionality. The number of servers (n) needed to tolerate `f` failures is then `n = 2 x f + 1`.

In practice this means that to tolerate one failure the group must have three servers in it. As such if one server fails, there are still two servers to form a majority (two out of three) and allow the system to continue to make decisions automatically and progress. However, if a second server fails *involuntarily*, then the group (with one server left) blocks, because there is no majority to reach a decision.

The following is a small table illustrating the formula above.

Group Size	Majority	Failures Tolerated
1	1	0
2	2	0
3	2	1
4	3	1
5	3	2
6	4	2
7	4	3

The next Chapter covers technical aspects of Group Replication.

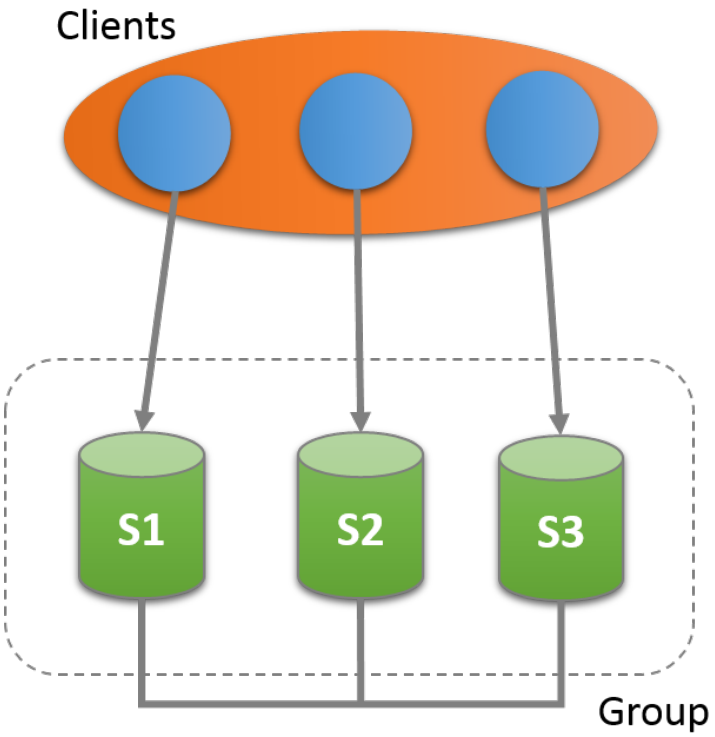
18.2 Getting Started

MySQL Group Replication is provided as a plugin to MySQL server, and each server in a group requires configuration and installation of the plugin. This section provides a detailed tutorial with the steps required to create a replication group with at least three servers.

18.2.1 Deploying Group Replication in Single-Primary Mode

Each of the server instances in a group can run on an independent physical machine, or on the same machine. This section explains how to create a replication group with three MySQL Server instances on one physical machine. This means that three data directories are needed, one per server instance, and that you need to configure each instance independently.

Figure 18.4 Group Architecture



This tutorial explains how to get and deploy MySQL Server with the Group Replication plugin, how to configure each server instance before creating a group, and how to use Performance Schema monitoring to verify that everything is working correctly.

18.2.1.1 Deploying Instances for Group Replication

The first step is to deploy three instances of MySQL Server. Group Replication is a built-in MySQL plugin provided with MySQL Server 8.0. For more background information on MySQL plugins, see Section 5.6, “MySQL Server Plugins”. This procedure assumes that MySQL Server was downloaded and unpacked into the directory named `mysql-8.0`. The following procedure uses one physical machine, therefore each MySQL server instance requires a specific data directory for the instance. Create the data directories in a directory named `data` and initialize each one.

```
mkdir data
mysql-8.0/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-8.0 --datadir=$PWD/data/s1
mysql-8.0/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-8.0 --datadir=$PWD/data/s2
mysql-8.0/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-8.0 --datadir=$PWD/data/s3
```

Inside `data/s1`, `data/s2`, `data/s3` is an initialized data directory, containing the mysql system database and related tables and much more. To learn more about the initialization procedure, see Section 2.10.1, “Initializing the Data Directory”.

Warning

Do not use `--initialize-insecure` in production environments, it is only used here to simplify the tutorial. For more information on security settings, see Section 18.5, “Group Replication Security”.

18.2.1.2 Configuring an Instance for Group Replication

This section explains the configuration settings required for MySQL Server instances that you want to use for Group Replication. For background information, see Section 18.9.2, “Group Replication Limitations”.

Group Replication Server Settings

To install and use the Group Replication plugin you must configure the MySQL Server instance correctly. It is recommended to store the configuration in the instance's configuration file. See Section 4.2.7, “Using Option Files” for more information. Unless stated otherwise, what follows is the configuration for the first instance in the group, referred to as *s1* in this procedure. The following section shows an example server configuration.

```
[mysqld]

# server configuration
datadir=<full_path_to_data>/data/s1
basedir=<full_path_to_bin>/mysql-8.0/

port=24801
socket=<full_path_to_sock_dir>/s1.sock
```

These settings configure MySQL server to use the data directory created earlier and which port the server should open and start listening for incoming connections.

Note

The non-default port of 24801 is used because in this tutorial the three server instances use the same hostname. In a setup with three different machines this would not be required.

Group Replication requires a network connection between the members, which means that each member must be able to resolve the network address of all of the other members. For example in this tutorial all three instances run on one machine, so to ensure that the members can contact each other you could add a line to the option file such as `report_host=127.0.0.1`.

Replication Framework

The following settings configure replication according to the MySQL Group Replication requirements.

```
server_id=1
gtid_mode=ON
enforce_gtid_consistency=ON
binlog_checksum=NONE
```

These settings configure the server to use the unique identifier number 1, to enable global transaction identifiers, to allow execution of only statements that can be safely logged using a GTID, and to disable writing checksums for events written to the binary log.

If you are using a version of MySQL earlier than 8.0.3, where the defaults were improved for replication, you need to add these lines to the member's option file.

```
log_bin=binlog
log_slave_updates=ON
binlog_format=ROW
master_info_repository=TABLE
```

```
relay_log_info_repository=TABLE
```

These settings instruct the server to turn on binary logging, use row-based format, to store replication metadata in system tables instead of files and disable binary log event checksums. For more details see Section 18.9.1, “Group Replication Requirements”.

Group Replication Settings

At this point the `my.cnf` file ensures that the server is configured and is instructed to instantiate the replication infrastructure under a given configuration. The following section configures the Group Replication settings for the server.

```
transaction_write_set_extraction=XXHASH64
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "127.0.0.1:24901"
group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
group_replication_bootstrap_group=off
```

- Configuring `transaction_write_set_extraction` instructs the server that for each transaction it has to collect the write set and encode it as a hash using the XXHASH64 hashing algorithm. From MySQL 8.0.2, this setting is the default, so this line can be omitted.
- Configuring `group_replication_group_name` tells the plugin that the group that it is joining, or creating, is named "aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa".

  The value of `group_replication_group_name` must be a valid UUID. This UUID is used internally when setting GTIDs for Group Replication events in the binary log. Use `SELECT UUID()` to generate a UUID.
- Configuring `group_replication_start_on_boot` instructs the plugin to not start operations automatically when the server starts. This is important when setting up Group Replication as it ensures you can configure the server before manually starting the plugin. Once the member is configured you can set `group_replication_start_on_boot` to on so that Group Replication starts automatically upon server boot.
- Configuring `group_replication_local_address` tells the plugin to use the network address 127.0.0.1 and port 24901 for internal communication with other members in the group.

  Important

  Group Replication uses this address for internal member-to-member connections involving remote instances of the group communication engine (XCom, a Paxos variant). This address must be different to the hostname and port used for SQL and it must not be used for client applications. It must be reserved for internal communication between the members of the group while running Group Replication.

  The network address configured by `group_replication_local_address` must be resolvable by all group members. For example, if each server instance is on a different machine with a fixed network address, you could use the IP address of the machine, such as 10.0.0.1. If you use a host name, you must use a fully qualified name, and ensure it is resolvable through DNS, correctly configured `/etc/hosts` files, or other name resolution processes. From MySQL 8.0.14, IPv6 addresses (or host names that resolve to them) can be used as well as IPv4 addresses. A group can contain a mix of members using IPv6 and members using IPv4. For more information on Group Replication support for IPv6 networks and on mixed IPv4 and IPv6 groups, see Section 18.4.6, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”.

  The recommended port for `group_replication_local_address` is 33061. In this tutorial we use three server instances running on one machine, thus ports 24901 to 24903 are used for the internal communication network address. `group_replication_local_address` is used by Group Replication as the unique identifier for a group member within the replication group. You can

use the same port for all members of a replication group as long as the host names or IP addresses are all different, and as demonstrated in this tutorial, you can use the same host name or IP address for all members as long as the ports are all different.

- Configuring `group_replication_group_seeds` sets the hostname and port of the group members which are used by the new member to establish its connection to the group. These members are called the seed members. Once the connection is established, the group membership information is listed at `performance_schema.replication_group_members`. Usually the `group_replication_group_seeds` list contains the `hostname:port` of each of the group member's `group_replication_local_address`, but this is not obligatory and a subset of the group members can be chosen as seeds.

  Important

  The `hostname:port` listed in `group_replication_group_seeds` is the seed member's internal network address, configured by `group_replication_local_address` and not the SQL `hostname:port` used for client connections, and shown for example in `performance_schema.replication_group_members` table.

  The server that starts the group does not make use of this option, since it is the initial server and as such, it is in charge of bootstrapping the group. In other words, any existing data which is on the server bootstrapping the group is what is used as the data for the next joining member. The second server joining asks the one and only member in the group to join, any missing data on the second server is replicated from the donor data on the bootstrapping member, and then the group expands. The third server joining can ask any of these two to join, data is synchronized to the new member, and then the group expands again. Subsequent servers repeat this procedure when joining.

  Warning

  When joining multiple servers at the same time, make sure that they point to seed members that are already in the group. Do not use members that are also joining the group as seeds, because they may not yet be in the group when contacted.

  It is good practice to start the bootstrap member first, and let it create the group. Then make it the seed member for the rest of the members that are joining. This ensures that there is a group formed when joining the rest of the members.

  Creating a group and joining multiple members at the same time is not supported. It may work, but chances are that the operations race and then the act of joining the group ends up in an error or a time out.

  A joining member must communicate with a seed member using the same protocol (IPv4 or IPv6) that the seed member advertises in the `group_replication_group_seeds` option. For the purpose of IP address whitelisting for Group Replication, the whitelist on the seed member must include an IP address for the joining member for the protocol offered by the seed member, or a host name that resolves to an address for that protocol. This address or host name must be set up and whitelisted in addition to the joining member's `group_replication_local_address` if the protocol for that address does not match the seed member's advertised protocol. If a joining member does not have a whitelisted address for the appropriate protocol, its connection attempt is refused. For more information, see Section 18.5.1, “IP Address Whitelisting”.

- Configuring `group_replication_bootstrap_group` instructs the plugin whether to bootstrap the group or not.

Important

This option must only be used on one server instance at any time, usually the first time you bootstrap the group (or in case the entire group is brought down and back up again). If you bootstrap the group multiple times, for example when multiple server instances have this option set, then they could create an artificial split brain scenario, in which two distinct groups with the same name exist. Disable this option after the first server instance comes online.

Configuration for all servers in the group is quite similar. You need to change the specifics about each server (for example `server_id`, `datadir`, `group_replication_local_address`). This is illustrated later in this tutorial.

18.2.1.3 User Credentials

Group Replication uses the asynchronous replication protocol to achieve Section 18.11.5, “Distributed Recovery”, synchronizing group members before joining them to the group. The distributed recovery process relies on a replication channel named `group_replication_recovery` which is used to transfer transactions from donor members to members that join the group. Therefore you need to set up a replication user with the correct permissions so that Group Replication can establish direct member-to-member recovery replication channels.

Start the server using the options file:

```
mysql-8.0/bin/mysqld --defaults-file=data/s1/s1.cnf
```

Create a MySQL user with the `REPLICATION-SLAVE` privilege. This process can be captured in the binary log and then you can rely on distributed recovery to replicate the statements used to create the user. Alternatively, you can disable binary logging and then create the user manually on each member, for example if you want to avoid the changes being propagated to other server instances. To disable binary logging, connect to server s1 and issue the following statements:

```
mysql> SET SQL_LOG_BIN=0;
```

In the following example the user *`rpl_user`* with the password *`password`* is shown. When configuring your servers use a suitable user name and password.

```
mysql> CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
mysql> FLUSH PRIVILEGES;
```

If binary logging was disabled, enable it again once the user has been created.

```
mysql> SET SQL_LOG_BIN=1;
```

Once the user has been configured, use the `CHANGE MASTER TO` statement to configure the server to use the given credentials for the `group_replication_recovery` replication channel the next time it needs to recover its state from another member. Issue the following, replacing *`rpl_user`* and *`password`* with the values used when creating the user.

```
mysql> CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' \\
       FOR CHANNEL 'group_replication_recovery';
```

Distributed recovery is the first step taken by a server that joins the group and does not have the same set of transactions as the group members. If these credentials are not set correctly for the `group_replication_recovery` replication channel and the `rpl_user` as shown, the server cannot connect to the donor members and run the distributed recovery process to gain synchrony with the other group members, and hence ultimately cannot join the group.

Similarly, if the server cannot correctly identify the other members via the server's `hostname` the recovery process can fail. It is recommended that operating systems running MySQL have a properly configured unique `hostname`, either using DNS or local settings. This `hostname` can be verified in the `Member_host` column of the `performance_schema.replication_group_members` table. If multiple group members externalize a default `hostname` set by the operating system, there is a chance of the member not resolving to the correct member address and not being able to join the group. In such a situation use `report_host` to configure a unique `hostname` to be externalized by each of the servers.

Using Group Replication and the Caching SHA-2 User Credentials Plugin

By default, users created in MySQL 8 use Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication”. If the *`rpl_user`* you configure for distributed recovery uses the caching SHA-2 authentication plugin and you are not using Section 18.5.2, “Secure Socket Layer Support (SSL)” for the `group_replication_recovery` replication channel, RSA key-pairs are used for password exchange, see Section 6.4.3, “Creating SSL and RSA Certificates and Keys”. You can either copy the public key of the `rpl_user` to the member that should recover its state from the group, or configure the donors to provide the public key when requested.

The more secure approach is to copy the public key of the `rpl_user` to the member that should recover the group state from the donors. Then you need to configure the `group_replication_recovery_public_key_path` system variable on the member joining the group with the path to the public key for the `rpl_user`.

Optionally, a less secure approach is to set `group_replication_recovery_get_public_key=ON` on donors so that they provide the public key of the `rpl_user` to members when they join the group. There is no way to verify the identity of a server, therefore only set `group_replication_recovery_get_public_key=ON` when you are sure there is no risk of server identity being compromised, for example by a man-in-the-middle attack.

18.2.1.4 Launching Group Replication

Once server s1 has been configured and started, install the Group Replication plugin. Connect to the server and issue the following command:

```
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

Important

The `mysql.session` user must exist before you can load Group Replication. `mysql.session` was added in MySQL version 8.0.2. If your data dictionary was initialized using an earlier version you must perform the MySQL upgrade procedure (see Section 2.11, “Upgrading MySQL”). If the upgrade is not run, Group Replication fails to start with the error message `There was an error when trying to access the server with user: mysql.session@localhost. Make sure the user is present in the server and that mysql_upgrade was ran after a server update.`.

To check that the plugin was installed successfully, issue `SHOW PLUGINS;` and check the output. It should show something like this:

```
mysql> SHOW PLUGINS;
+----------------------------+----------+--------------------+----------------------+-------------+
| Name                       | Status   | Type               | Library              | License     |
+----------------------------+----------+--------------------+----------------------+-------------+
| binlog                     | ACTIVE   | STORAGE ENGINE     | NULL                 | PROPRIETARY |

(...)
```

```
| group_replication          | ACTIVE   | GROUP REPLICATION  | group_replication.so | PROPRIETARY |
+----------------------------+----------+--------------------+----------------------+-------------+
```

To start the group, instruct server s1 to bootstrap the group and then start Group Replication. This bootstrap should only be done by a single server, the one that starts the group and only once. This is why the value of the bootstrap configuration option was not saved in the configuration file. If it is saved in the configuration file, upon restart the server automatically bootstraps a second group with the same name. This would result in two distinct groups with the same name. The same reasoning applies to stopping and restarting the plugin with this option set to `ON`.

```
SET GLOBAL group_replication_bootstrap_group=ON;
START GROUP_REPLICATION;
SET GLOBAL group_replication_bootstrap_group=OFF;
```

Once the `START GROUP_REPLICATION` statement returns, the group has been started. You can check that the group is now created and that there is one member in it:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+---------------------------+--------------------------------------+-------------+-------------+-------
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER
+---------------------------+--------------------------------------+-------------+-------------+-------
| group_replication_applier | ce9be252-2b71-11e6-b8f4-00212844f856 | myhost      |       24801 | ONLINE
+---------------------------+--------------------------------------+-------------+-------------+-------
```

The information in this table confirms that there is a member in the group with the unique identifier `ce9be252-2b71-11e6-b8f4-00212844f856`, that it is `ONLINE` and is at `myhost` listening for client connections on port `24801`.

For the purpose of demonstrating that the server is indeed in a group and that it is able to handle load, create a table and add some content to it.

```
mysql> CREATE DATABASE test;
mysql> USE test;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 TEXT NOT NULL);
mysql> INSERT INTO t1 VALUES (1, 'Luis');
```

Check the content of table `t1` and the binary log.

```
mysql> SELECT * FROM t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 | Luis |
+----+------+

mysql> SHOW BINLOG EVENTS;
+---------------+-----+----------------+-----------+-------------+-----------------------------------
| Log_name      | Pos | Event_type     | Server_id | End_log_pos | Info
+---------------+-----+----------------+-----------+-------------+-----------------------------------
| binlog.000001 |   4 | Format_desc    |         1 |         123 | Server ver: 8.0.2-gr080-log, Binlog
| binlog.000001 | 123 | Previous_gtids |         1 |         150 |
| binlog.000001 | 150 | Gtid           |         1 |         211 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-a
| binlog.000001 | 211 | Query          |         1 |         270 | BEGIN
| binlog.000001 | 270 | View_change    |         1 |         369 | view_id=14724817264259180:1
| binlog.000001 | 369 | Query          |         1 |         434 | COMMIT
| binlog.000001 | 434 | Gtid           |         1 |         495 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-a
| binlog.000001 | 495 | Query          |         1 |         585 | CREATE DATABASE test
| binlog.000001 | 585 | Gtid           |         1 |         646 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-a
| binlog.000001 | 646 | Query          |         1 |         770 | use `test`; CREATE TABLE t1 (c1 INT
| binlog.000001 | 770 | Gtid           |         1 |         831 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-a
| binlog.000001 | 831 | Query          |         1 |         899 | BEGIN
| binlog.000001 | 899 | Table_map      |         1 |         942 | table_id: 108 (test.t1)
| binlog.000001 | 942 | Write_rows     |         1 |         984 | table_id: 108 flags: STMT_END_F
| binlog.000001 | 984 | Xid            |         1 |        1011 | COMMIT /* xid=38 */
```

```
+--------------+-----+---------------+-----------+------------+-----------------------------------
```

As seen above, the database and the table objects were created and their corresponding DDL statements were written to the binary log. Also, the data was inserted into the table and written to the binary log. The importance of the binary log entries is illustrated in the following section when the group grows and distributed recovery is executed as new members try to catch up and become online.

18.2.1.5 Adding Instances to the Group

At this point, the group has one member in it, server s1, which has some data in it. It is now time to expand the group by adding the other two servers configured previously.

Adding a Second Instance

In order to add a second instance, server s2, first create the configuration file for it. The configuration is similar to the one used for server s1, except for things such as the location of the data directory, the ports that s2 is going to be listening on or its `server_id`. These different lines are highlighted in the listing below.

```
[mysqld]

# server configuration
datadir=<full_path_to_data>/data/s2
basedir=<full_path_to_bin>/mysql-8.0/

port=24802
socket=<full_path_to_sock_dir>/s2.sock

#
# Replication configuration parameters
#
server_id=2
gtid_mode=ON
enforce_gtid_consistency=ON
binlog_checksum=NONE

#
# Group Replication configuration
#
transaction_write_set_extraction=XXHASH64
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "127.0.0.1:24902"
group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
group_replication_bootstrap_group= off
```

Similar to the procedure for server s1, with the option file in place you launch the server.

```
mysql-8.0/bin/mysqld --defaults-file=data/s2/s2.cnf
```

Then configure the recovery credentials as follows. The commands are the same as used when setting up server s1 as the user is shared within the group. Issue the following statements on s2.

```
SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
SET SQL_LOG_BIN=1;
CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' \\
 FOR CHANNEL 'group_replication_recovery';
```

Tip

If you are using the caching SHA-2 authentication plugin, the default in MySQL 8, see Using Group Replication and the Caching SHA-2 User Credentials Plugin.

Install the Group Replication plugin and start the process of joining the server to the group. The following example installs the plugin in the same way as used while deploying server s1.

```
mysql> INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

Add server s2 to the group.

```
mysql> START GROUP_REPLICATION;
```

Unlike the previous steps that were the same as those executed on s1, here there is a difference in that you do *not* issue `SET GLOBAL group_replication_bootstrap_group=ON;` before starting Group Replication, because the group has already been created and bootstrapped by server s1. At this point server s2 only needs to be added to the already existing group.

Tip

When Group Replication starts successfully and the server joins the group it checks the `super_read_only` variable. By setting `super_read_only` to ON in the member's configuration file, you can ensure that servers which fail when starting Group Replication for any reason do not accept transactions. If the server should join the group as read-write instance, for example as the primary in a single-primary group or as a member of a multi-primary group, when the `super_read_only` variable is set to ON then it is set to OFF upon joining the group.

Checking the `performance_schema.replication_group_members` table again shows that there are now two *ONLINE* servers in the group.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+---------------------------+--------------------------------------+-------------+-------------+-------
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER
+---------------------------+--------------------------------------+-------------+-------------+-------
| group_replication_applier | 395409e1-6dfa-11e6-970b-00212844f856 | myhost      |       24801 | ONLINE
| group_replication_applier | ac39f1e6-6dfa-11e6-a69d-00212844f856 | myhost      |       24802 | ONLINE
+---------------------------+--------------------------------------+-------------+-------------+-------
```

As server s2 is also marked as ONLINE, it must have already caught up with server s1 automatically. Verify that it has indeed synchronized with server s1 as follows.

```
mysql> SHOW DATABASES LIKE 'test';
+-----------------+
| Database (test) |
+-----------------+
| test            |
+-----------------+

mysql> SELECT * FROM test.t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 | Luis |
+----+------+

mysql> SHOW BINLOG EVENTS;
+---------------+------+----------------+-----------+-------------+-----------------------------------
| Log_name      | Pos  | Event_type     | Server_id | End_log_pos | Info
+---------------+------+----------------+-----------+-------------+-----------------------------------
| binlog.000001 |    4 | Format_desc    |         2 |         123 | Server ver: 8.0.3-log, Binlog ver:
| binlog.000001 |  123 | Previous_gtids |         2 |         150 |
| binlog.000001 |  150 | Gtid           |         1 |         211 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-
| binlog.000001 |  211 | Query          |         1 |         270 | BEGIN
| binlog.000001 |  270 | View_change    |         1 |         369 | view_id=14724832985483517:1
| binlog.000001 |  369 | Query          |         1 |         434 | COMMIT
```

```
| binlog.000001 |  434 | Gtid           |         1 |         495 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa
| binlog.000001 |  495 | Query          |         1 |         585 | CREATE DATABASE test
| binlog.000001 |  585 | Gtid           |         1 |         646 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa
| binlog.000001 |  646 | Query          |         1 |         770 | use `test`; CREATE TABLE t1 (c1 INT PRI
| binlog.000001 |  770 | Gtid           |         1 |         831 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa
| binlog.000001 |  831 | Query          |         1 |         890 | BEGIN
| binlog.000001 |  890 | Table_map      |         1 |         933 | table_id: 108 (test.t1)
| binlog.000001 |  933 | Write_rows     |         1 |         975 | table_id: 108 flags: STMT_END_F
| binlog.000001 |  975 | Xid            |         1 |        1002 | COMMIT /* xid=30 */
| binlog.000001 | 1002 | Gtid           |         1 |        1063 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa
| binlog.000001 | 1063 | Query          |         1 |        1122 | BEGIN
| binlog.000001 | 1122 | View_change    |         1 |        1261 | view_id=14724832985483517:2
| binlog.000001 | 1261 | Query          |         1 |        1326 | COMMIT
+---------------+------+----------------+-----------+-------------+-------------------------------------
```

As seen above, the second server has been added to the group and it has replicated the changes from server s1 automatically. According to the distributed recovery procedure, this means that just after joining the group and immediately before being declared online, server s2 has connected to server s1 automatically and fetched the missing data from it. In other words, it copied transactions from the binary log of s1 that it was missing, up to the point in time that it joined the group.

Adding Additional Instances

Adding additional instances to the group is essentially the same sequence of steps as adding the second server, except that the configuration has to be changed as it had to be for server s2. To summarise the required commands:

1. Create the configuration file

```
[mysqld]

# server configuration
datadir=<full_path_to_data>/data/s3
basedir=<full_path_to_bin>/mysql-8.0/

port=24803
socket=<full_path_to_sock_dir>/s3.sock

#
# Replication configuration parameters
#
server_id=3
gtid_mode=ON
enforce_gtid_consistency=ON
binlog_checksum=NONE

#
# Group Replication configuration
#
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "127.0.0.1:24903"
group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
group_replication_bootstrap_group= off
```

2. Start the server

```
mysql-8.0/bin/mysqld --defaults-file=data/s3/s3.cnf
```

3. Configure the recovery credentials for the group_replication_recovery channel.

```
SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
FLUSH PRIVILEGES;
```

```
SET SQL_LOG_BIN=1;
CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password'  \\
FOR CHANNEL 'group_replication_recovery';
```

4. Install the Group Replication plugin and start it.

```
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
START GROUP_REPLICATION;
```

At this point server s3 is booted and running, has joined the group and caught up with the other servers in the group. Consulting the `performance_schema.replication_group_members` table again confirms this is the case.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+---------------------------+--------------------------------------+-------------+-------------+-------
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER
+---------------------------+--------------------------------------+-------------+-------------+-------
| group_replication_applier | 395409e1-6dfa-11e6-970b-00212844f856 | myhost      |       24801 | ONLINE
| group_replication_applier | 7eb217ff-6df3-11e6-966c-00212844f856 | myhost      |       24803 | ONLINE
| group_replication_applier | ac39f1e6-6dfa-11e6-a69d-00212844f856 | myhost      |       24802 | ONLINE
+---------------------------+--------------------------------------+-------------+-------------+-------
```

Issuing this same query on server s2 or server s1 yields the same result. Also, you can verify that server s3 has also caught up:

```
mysql> SHOW DATABASES LIKE 'test';
+-----------------+
| Database (test) |
+-----------------+
| test            |
+-----------------+

mysql> SELECT * FROM test.t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 | Luis |
+----+------+

mysql> SHOW BINLOG EVENTS;
+---------------+------+----------------+-----------+-------------+-----------------------------------
| Log_name      | Pos  | Event_type     | Server_id | End_log_pos | Info
+---------------+------+----------------+-----------+-------------+-----------------------------------
| binlog.000001 |    4 | Format_desc    |         3 |         123 | Server ver: 8.0.3-log, Binlog ver:
| binlog.000001 |  123 | Previous_gtids |         3 |         150 |
| binlog.000001 |  150 | Gtid           |         1 |         211 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-
| binlog.000001 |  211 | Query          |         1 |         270 | BEGIN
| binlog.000001 |  270 | View_change    |         1 |         369 | view_id=14724832985483517:1
| binlog.000001 |  369 | Query          |         1 |         434 | COMMIT
| binlog.000001 |  434 | Gtid           |         1 |         495 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-
| binlog.000001 |  495 | Query          |         1 |         585 | CREATE DATABASE test
| binlog.000001 |  585 | Gtid           |         1 |         646 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-
| binlog.000001 |  646 | Query          |         1 |         770 | use `test`; CREATE TABLE t1 (c1 INT
| binlog.000001 |  770 | Gtid           |         1 |         831 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-
| binlog.000001 |  831 | Query          |         1 |         890 | BEGIN
| binlog.000001 |  890 | Table_map      |         1 |         933 | table_id: 108 (test.t1)
| binlog.000001 |  933 | Write_rows     |         1 |         975 | table_id: 108 flags: STMT_END_F
| binlog.000001 |  975 | Xid            |         1 |        1002 | COMMIT /* xid=29 */
| binlog.000001 | 1002 | Gtid           |         1 |        1063 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-
| binlog.000001 | 1063 | Query          |         1 |        1122 | BEGIN
| binlog.000001 | 1122 | View_change    |         1 |        1261 | view_id=14724832985483517:2
| binlog.000001 | 1261 | Query          |         1 |        1326 | COMMIT
| binlog.000001 | 1326 | Gtid           |         1 |        1387 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-
| binlog.000001 | 1387 | Query          |         1 |        1446 | BEGIN
| binlog.000001 | 1446 | View_change    |         1 |        1585 | view_id=14724832985483517:3
| binlog.000001 | 1585 | Query          |         1 |        1650 | COMMIT
+---------------+------+----------------+-----------+-------------+-----------------------------------
```

18.3 Monitoring Group Replication

Use the Perfomance Schema tables to monitor Group Replication, assuming that the Performance Schema is enabled. Group Replication adds the following tables:

- `performance_schema.replication_group_member_stats`
- `performance_schema.replication_group_members`

These Perfomance Schema replication tables also show information about Group Replication:

- `performance_schema.replication_connection_status` shows information regarding Group Replication, for example the transactions that have been received from the group and queued in the applier queue (the relay log).
- `performance_schema.replication_applier_status` shows the state of the Group Replication related channels and threads If there are many different worker threads applying transactions, then the worker tables can also be used to monitor what each worker thread is doing.

The replication channels created by the Group Replication plugin are named:

- `group_replication_recovery` - This channel is used for the replication changes that are related to the distributed recovery phase.
- `group_replication_applier` - This channel is used for the incoming changes from the group. This is the channel used to apply transactions coming directly from the group.

The following sections describe how to interpret the information available.

18.3.1 Group Replication Server States

There are various states that a server instance can be in. If servers are communicating properly, all report the same states for all servers. However, if there is a network partition, or a server leaves the group, then different information could be reported, depending on which server is queried. If the server has left the group then it cannot report updated information about the other servers' states. If there is a partition, such that quorum is lost, servers are not able to coordinate between themselves. As a consequence, they cannot guess what the status of different servers is. Therefore, instead of guessing their state they report that some servers are unreachable.

Table 18.1 Server State

Field	Description	Group Synchronized
`ONLINE`	The member is ready to serve as a fully functional group member, meaning that the client can connect and start executing transactions.	Yes
`RECOVERING`	The member is in the process of becoming an active member of the group and is currently going through the recovery process, receiving state information from a donor.	No
`OFFLINE`	The plugin is loaded but the member does not belong to any group.	No
`ERROR`	The state of the member. Whenever there is an error on the recovery phase or while applying changes, the server enters this state.	No
`UNREACHABLE`	Whenever the local failure detector suspects that a given server is not reachable, because	No

Field	Description	Group Synchronized
	for example it was disconnected involuntarily, it shows that server's state as `UNREACHABLE`.	

Important

Once an instance enters `ERROR` state, the `super_read_only` option is set to `ON`. To leave the `ERROR` state you must manually configure the instance with `super_read_only=OFF`.

Note that Group Replication is *not* synchronous, but eventually synchronous. More precisely, transactions are delivered to all group members in the same order, but their execution is not synchronized, meaning that after a transaction is accepted to be committed, each member commits at its own pace.

18.3.2 The replication_group_members Table

The `performance_schema.replication_group_members` table is used for monitoring the status of the different server instances that are members of the group. The information in the table is updated whenever there is a view change, for example when the configuration of the group is dynamically changed when a new member joins. At that point, servers exchange some of their metadata to synchronize themselves and continue to cooperate together. The information is shared between all the server instances that are members of the replication group, so information on all the group members can be queried from any member. This table can be used to get a high level view of the state of a replication group, for example by issuing:

```
SELECT * FROM performance_schema.replication_group_members;
+---------------------------+--------------------------------------+--------------+-------------+------
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST  | MEMBER_PORT | MEMBE
+---------------------------+--------------------------------------+--------------+-------------+------
| group_replication_applier | 041f26d8-f3f3-11e8-adff-080027337932 | example1     |        3306 | ONLIN
| group_replication_applier | f60a3e10-f3f2-11e8-8258-080027337932 | example2     |        3306 | ONLIN
| group_replication_applier | fc890014-f3f2-11e8-a9fd-080027337932 | example3     |        3306 | ONLIN
+---------------------------+--------------------------------------+--------------+-------------+------
```

Based on this result we can see that the group consists of three members, each member's host and port number which clients use to connect to the member, and the `server_uuid` of the member. The `MEMBER_STATE` column shows one of the Section 18.3.1, “Group Replication Server States”, in this case it shows that all three members in this group are `ONLINE`, and the `MEMBER_ROLE` column shows that there are two secondaries, and a single primary. Therefore this group must be running in single-primary mode. The `MEMBER_VERSION` column can be useful when you are upgrading a group and are combining members running different MySQL versions. See Section 18.3.1, “Group Replication Server States” for more information.

For more information about the `Member_host` value and its impact on the distributed recovery process, see Section 18.2.1.3, “User Credentials”.

18.3.3 Replication_group_member_stats

Each member in a replication group certifies and applies transactions received by the group. Statistics regarding the certifier and applier procedures are useful to understand how the applier queue is growing, how many conflicts have been found, how many transactions were checked, which transactions are committed everywhere, and so on.

The `performance_schema.replication_group_member_stats` table provides group-level information related to the certification process, and also statistics for the transactions received and originated by each individual member of the replication group. The information is shared between all the server instances that are members of the replication group, so information on all the group members can be queried from any member. Note that refreshing of statistics for remote members is

controlled by the message period specified in the `group_replication_flow_control_period` option, so these can differ slightly from the locally collected statistics for the member where the query is made.

Table 18.2 replication_group_member_stats

Field	Description
Channel_name	The name of the Group Replication channel.
View_id	The current view identifier for this group.
Member_id	The member server UUID. This has a different value for each member in the group. This also serves as a key because it is unique to each member.
Count_transactions_in_queue	The number of transactions in the queue pending conflict detection checks. Once the transactions have been checked for conflicts, if they pass the check, they are queued to be applied as well.
Count_transactions_checked	The number of transactions that have been checked for conflicts.
Count_conflicts_detected	The number of transactions that did not pass the conflict detection check.
Count_transactions_rows_validating	The current size of the conflict detection database (against which each transaction is certified).
Transactions_committed_all_members	The transactions that have been successfully committed on all members of the replication group. This is updated at a fixed time interval.
Last_conflict_free_transaction	The transaction identifier of the last conflict free transaction checked.
Count_transactions_remote_in_applier_queue	The number of transactions that this member has received from the replication group which are waiting to be applied.
Count_transactions_remote_applied	The number of transactions that this member has received from the replication group which have been applied.
Count_transactions_local_proposed	The number of transactions that this member originated and sent to the replication group for coordination.
Count_transactions_local_rollback	The number of transactions that this member originated that were rolled back after being sent to the replication group.

These fields are important for monitoring the performance of the members connected in the group. For example, suppose that one of the group's members is delayed and is not able to keep up to date with the other members of the group. In this case you might see a large number of transactions in the queue. Based on this information, you could decide to either remove the member from the group, or delay the processing of transactions on the other members of the group in order to reduce the number of queued transactions. This information can also help you to decide how to adjust the flow control of the Group Replication plugin.

18.4 Group Replication Operations

This section describes the different modes of deploying Group Replication, explains common operations for managing groups and provides information about how to tune your groups. .

18.4.1 Deploying in Multi-Primary or Single-Primary Mode

Group Replication operates in the following different modes:

- single-primary mode

- multi-primary mode

The default mode is single-primary. It is not possible to have members of the group deployed in different modes, for example one configured in multi-primary mode while another one is in single-primary mode. To switch between modes, the group and not the server, needs to be restarted with a different operating configuration. Regardless of the deployed mode, Group Replication does not handle client-side fail-over, that must be handled by the application itself, a connector or a middleware framework such as a proxy or MySQL Router 8.0.

When deployed in multi-primary mode, statements are checked to ensure they are compatible with the mode. The following checks are made when Group Replication is deployed in multi-primary mode:

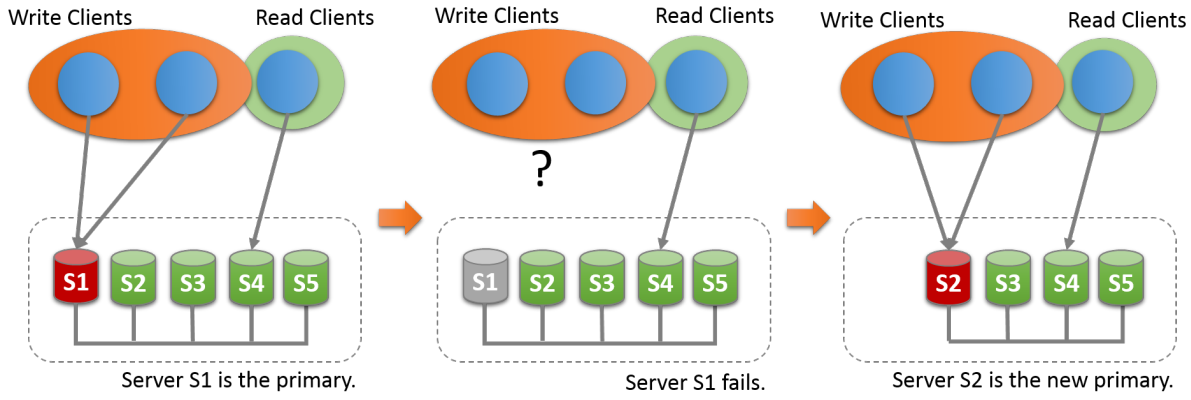
- If a transaction is executed under the SERIALIZABLE isolation level, then its commit fails when synchronizing itself with the group.
- If a transaction executes against a table that has foreign keys with cascading constraints, then the transaction fails to commit when synchronizing itself with the group.

These checks can be deactivated by setting the option `group_replication_enforce_update_everywhere_checks` to `FALSE`. When deploying in single-primary mode, this option *must* be set to `FALSE`.

18.4.1.1 Single-Primary Mode

In this mode the group has a single-primary server that is set to read-write mode. All the other members in the group are set to read-only mode (with `super-read-only=ON`). This happens automatically. The primary is typically the first server to bootstrap the group, all other servers that join automatically learn about the primary server and are set to read only.

Figure 18.5 New Primary Election



When in single-primary mode, some of the checks deployed in multi-primary mode are disabled, because the system enforces that only a single server writes to the group. For example, changes to tables that have cascading foreign keys are allowed, whereas in multi-primary mode they are not. Upon primary member failure, an automatic primary election mechanism chooses the new primary member. The election process is performed by looking at the new view, and ordering the potential new primaries based on the value of `group_replication_member_weight`. Assuming the group is operating with all members running the same MySQL version, then the member with the highest value for `group_replication_member_weight` is elected as the new primary. In the event that multiple servers have the same `group_replication_member_weight`, the servers are then prioritized based on their `server_uuid` in lexicographical order and by picking the first one. Once a new primary is elected, it is automatically set to read-write and the other secondaries remain as secondaries, and as such, read-only.

When a new primary is elected, it is only writable once it has processed all of the transactions that came from the old primary. This avoids possible concurrency issues between old transactions from the

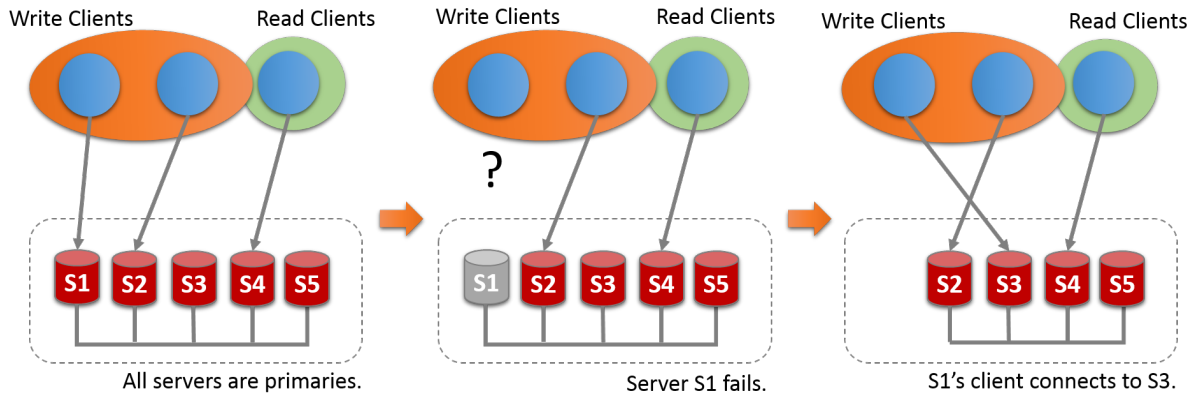
old primary and the new ones being executed on this member. It is a good practice to wait for the new primary to apply its replication related relay-log before re-routing client applications to it.

If the group is operating with members that are running different versions of MySQL then the election process can be impacted. For example, if any member does not support `group_replication_member_weight`, then the primary is chosen based on `server_uuid` order from the members of the lower major version. Alternatively, if all members running different MySQL versions do support `group_replication_member_weight`, the primary is chosen based on `group_replication_member_weight` from the members of the lower major version.

18.4.1.2 Multi-Primary Mode

In multi-primary mode, there is no notion of a single primary. There is no need to engage an election procedure because there is no server playing any special role.

Figure 18.6 Client Failover



All servers are set to read-write mode when joining the group.

18.4.1.3 Finding the Primary

To find out which server is currently the primary when deployed in single-primary mode, use the `MEMBER_ROLE` column in the `performance_schema.replication_group_members` table. For example:

```
mysql> SELECT MEMBER_HOST, MEMBER_ROLE FROM performance_schema.replication_group_members;
+--------------------------+-------------+
| MEMBER_HOST              | MEMBER_ROLE |
+--------------------------+-------------+
| remote1.example.com      | PRIMARY     |
| remote2.example.com      | SECONDARY   |
| remote3.example.com      | SECONDARY   |
+--------------------------+-------------+
```

Warning

The `group_replication_primary_member` status variable has been deprecated and is scheduled to be removed in a future version.

Alternatively use the `group_replication_primary_member` status variable.

```
mysql> SHOW STATUS LIKE 'group_replication_primary_member'
```

18.4.2 Configuring an Online Group

You can configure an online group while Group Replication is running by using a set of UDFs, which rely on a group action coordinator. These UDFs are installed by the Group Replication plugin in version

8.0.13 and higher. This section describes how changes are made to a running group, and the available UDFs.

Important

For the coordinator to be able to configure group wide actions on a running group, all members must be running MySQL 8.0.13 or later and have the UDFs installed.

To use the UDFs, connect to a member of the running group and issue the UDF with the `SELECT` statement. The Group Replication plugin processes the action and its parameters and the coordinator sends it to all members which are visible to the member where you issued the UDF. If the action is accepted, all members execute the action and send a termination message when completed. Once all members declare the action as finished, the invoking member returns the result to the client.

When configuring a whole group, the distributed nature of the operations means that they interact with many processes of the Group Replication plugin, and therefore you should observe the following:

You can issue configuration operations everywhere. If you want to make member A the new primary you do not need to invoke the operation on member A. All operations are sent and executed in a coordinated way on all group members. Also, this distributed execution of an operation has a different ramification: if the invoking member dies, any already running configuration process continues to run on other members. In the unlikely event that the invoking member dies, you can still use the monitoring features to ensure other members complete the operation successfully.

All members must be online. To simplify the migration or election processes and guarantee they are as fast as possible, the group must not contain any member in recovery, otherwise the configuration action is rejected by the member where you issue the statement.

No members can join a group during a configuration change. Any member that attempts to join the group during a coordinated configuration change leaves the group and cancels its join process.

Only one configuration at once. A group which is executing a configuration change cannot accept any other group configuration change, because concurrent configuration operations could lead to member divergence.

You cannot use configuration functions on mixed version groups. Due to the distributed nature of the these configuration actions, all members must recognize them in order to execute them. Therefore, no server of an older version can be present in the group, otherwise the operation is rejected.

18.4.2.1 Changing a Group's Primary Member

This section explains how to change which member of a single-primary group is the primary. The function used to change a group's mode can be run on any member.

Changing which Member is Primary

Use the `group_replication_set_as_primary()` UDF to change which member is the primary in a single-primary group. This function has no effect if issued on a member of a multi-primary group. Only a primary member can write to the group, so if an asynchronous channel is running on that member, no switch is allowed until the asynchronous channel is stopped. Pass in the `server_uuid` of the member which you want to become the new primary of the group by issuing:

```
SELECT group_replication_set_as_primary(member_uuid);
```

While the action runs, you can check its progress by issuing:

```
SELECT event_name, work_completed, work_estimated FROM performance_schema.events_stages_current WHERE e
+-------------------------------------------------------------------------------+----------------+--
```

```
| event_name                                                                                | work_completed | work_
+-------------------------------------------------------------------------------------------+----------------+------
| stage/group_rpl/Primary Election: Waiting for members to turn on super_read_only |              3 |
+-------------------------------------------------------------------------------------------+----------------+------
```

18.4.2.2 Changing a Group's Mode

This section explains how to change the mode which a group is running in, either single or multi-primary. The functions used to change a group's mode can be run on any member.

Changing to Single-Primary Mode

Use the `group_replication_switch_to_single_primary_mode()` UDF to change a group running in multi-primary mode to single-primary mode by issuing:

```
SELECT group_replication_switch_to_single_primary_mode()
```

If no string is passed in, the election of the new primary in the resulting single-primary group is controlled by the configured election weights, or UUID lexicographic order (see Section 18.4.1.1, "Single-Primary Mode"). While the action runs, you can check its progress by issuing:

```
SELECT event_name, work_completed, work_estimated FROM performance_schema.events_stages_current WHERE event
+-------------------------------------------------------------------------+----------------+------------
| event_name                                                              | work_completed | work_estima
+-------------------------------------------------------------------------+----------------+------------
| stage/group_rpl/Primary Switch: waiting for pending transactions to finish |              4 |
+-------------------------------------------------------------------------+----------------+------------
```

To override the election process and configure a specific member of the multi-primary group as the new primary in the process, get the `server_uuid` of the member and pass it to `group_replication_switch_to_single_primary_mode()`. For example issue:

```
SELECT group_replication_switch_to_single_primary_mode(member_uuid);
```

Changing to Multi-Primary Mode

Use the `group_replication_switch_to_multi_primary_mode()` UDF to change a group running in single-primary mode to multi-primary mode by issuing:

```
SELECT group_replication_switch_to_multi_primary_mode()
```

After some coordinated group operations to ensure the safety and consistency of your data, all members which belong to the group become primaries.

While the action runs, you can check its progress by issuing:

```
SELECT event_name, work_completed, work_estimated FROM performance_schema.events_stages_current WHERE event
+-----------------------------------------------------------------------+----------------+----------------+
| event_name                                                            | work_completed | work_estimated |
+-----------------------------------------------------------------------+----------------+----------------+
| stage/group_rpl/Multi-primary Switch: applying buffered transactions |              0 |              1 |
+-----------------------------------------------------------------------+----------------+----------------+
```

18.4.2.3 Using Group Replication Group Write Consensus

This section explains how to inspect and configure the maximum number of consensus instances at any time for a group. This maximum is referred to as the event horizon for a group, and is the maximum number of consensus instances that the group can execute in parallel. This enables you to fine tune the performance of your Group Replication deployment. For example, the default value of 10 is suitable for a group running on a LAN, but for groups operating over a slower network such as a WAN, increase this number to improve performance.

Inspecting a Group's Write Concurrency

Use the `group_replication_get_write_concurrency()` UDF to inspect a group's event horizon value at runtime by issuing:

```
SELECT group_replication_get_write_concurrency();
```

Configuring a Group's Write Concurrency

Use the `group_replication_set_write_concurrency()` UDF to set the maximum number of consensus instances that the system can execute in parallel by issuing:

```
SELECT group_replication_set_write_concurrency(instances);
```

where *`instances`* is the new maximum number of consensus instances.

18.4.2.4 Setting a Group's Communication Protocol Version

From MySQL 8.0.16, Group Replication has the concept of a communication protocol for the group. The Group Replication communication protocol version can be managed explicitly, and set to accommodate the oldest MySQL Server version that you want the group to support. This enables groups to be formed from members at different MySQL Server versions while ensuring backward compatibility. Versions from MySQL 5.7.14 allow compression of messages, and versions from MySQL 8.0.16 also allow fragmentation of messages. All members of the group must use the same communication protocol version, so that group members can be at different MySQL Server releases but only send messages that can be understood by all group members.

A MySQL server at version X can only join and reach `ONLINE` status in a replication group if the group's communication protocol version is less than or equal to X. When a new member joins a replication group, it checks the communication protocol version that is announced by the existing members of the group. If the joining member supports that version, it joins the group and uses the communication protocol that the group has announced, even if the member supports additional communication capabilities. If the joining member does not support the communication protocol version, it is expelled from the group.

If two members attempt to join in the same membership change event, they can only join if the communication protocol version for both members is already compatible with the group's communication protocol version. Members with different communication protocol versions from the group must join in isolation. For example:

- One MySQL Server 8.0.16 instance can successfully join a group that uses the communication protocol version 5.7.24.
- One MySQL Server 5.7.24 instance cannot successfully join a group that uses the communication protocol version 8.0.16.
- Two MySQL Server 8.0.16 instances cannot simultaneously join a group that uses the communication protocol version 5.7.24.
- Two MySQL Server 8.0.16 instances can simultaneously join a group that uses the communication protocol version 8.0.16.

You can inspect the communication protocol in use by a group by using the `group_replication_get_communication_protocol()` UDF, which returns the oldest MySQL Server version that the group supports. All existing members of the group return the same communication protocol version. For example:

```
SELECT group_replication_get_communication_protocol();
+-----------------------------------------------+
| group_replication_get_communication_protocol() |
```

```
+-----------------------------------------------+
| 8.0.16                                        |
+-----------------------------------------------+
```

Note that the `group_replication_get_communication_protocol()` UDF returns the minimum MySQL version that the group supports, which might differ from the version number that was passed to the `group_replication_set_communication_protocol()` UDF, and from the MySQL Server version that is installed on the member where you use the UDF.

If you need to change the communication protocol version of a group so that members at earlier releases can join, use the `group_replication_set_communication_protocol()` UDF to specify the MySQL Server version of the oldest member that you want to allow. This makes the group fall back to a compatible communication protocol version if possible. The `GROUP_REPLICATION_ADMIN` privilege is required to use this UDF, and all existing group members must be online when you issue the statement, with no loss of majority. For example:

```
SELECT group_replication_set_communication_protocol("5.7.25");
```

If you upgrade all the members of a replication group to a new MySQL Server release, the group's communication protocol version is not automatically upgraded to match. If you no longer need to support members at earlier releases, you can use the `group_replication_set_communication_protocol()` UDF to set the communication protocol version to the new MySQL Server version to which you have upgraded the members. For example:

```
SELECT group_replication_set_communication_protocol("8.0.16");
```

The `group_replication_set_communication_protocol()` UDF is implemented as a group action, so it is executed at the same time on all members of the group. The group action starts buffering messages and waits for delivery of any outgoing messages that were already in progress to complete, then changes the communication protocol version and sends the buffered messages. If a member attempts to join the group at any time after you change the communication protocol version, the group members announce the new protocol version.

MySQL InnoDB cluster automatically and transparently manages the communication protocol versions of its members, whenever the cluster topology is changed using AdminAPI operations. An InnoDB cluster always uses the most recent communication protocol version that is supported by all the instances that are currently part of the cluster or joining it.

- When an instance is added to, removed from, or rejoins the cluster, or a rescan or reboot operation is carried out on the cluster, the communication protocol version is automatically set to a version supported by the instance that is now at the earliest MySQL Server version.
- When you carry out a rolling upgrade by removing instances from the cluster, upgrading them, and adding them back into the cluster, the communication protocol version is automatically upgraded when the last remaining instance at the old MySQL Server version is removed from the cluster prior to its upgrade.

To see the communication protocol version in use in an InnoDB cluster, use the *`Cluster`*`.status()` function with the `'extended'` option enabled. The communication protocol version is returned in the `'GRProtocolVersion'` field, provided that the cluster has quorum and no cluster members are unreachable.

18.4.3 Transaction Consistency Guarantees

One of the major implications of a distributed system such as Group Replication is the consistency guarantees that it provides as a group. In other words, the consistency of the global synchronization of transactions distributed across the members of the group. This section describes how Group Replication handles consistency guarantees depending on the events that occur in a group, and how to best configure your group's consistency guarantees.

18.4.3.1 Understanding Transaction Consistency Guarantees

In terms of distributed consistency guarantees, either in normal or failure repair operations, Group Replication has always been an eventual consistency system. This means that as soon as the incoming traffic slows down or stops, all group members have the same data content. The events that relate to the consistency of a system can be split into control operations, either manual or automatically triggered by failures; and data flow operations.

For Group Replication, the control operations that can be evaluated in terms of consistency are:

- a member joining or leaving, which is covered by Group Replication's Section 18.11.5, “Distributed Recovery” and write protection.
- network failures, which are covered by the fencing modes.
- in single-primary groups, primary failover, which can also be an operation triggered by `group_replication_set_as_primary()`.

Consistency Guarantees and Primary Failover

In a single-primary group, in the event of a primary failover when a secondary is promoted to primary, the new primary can either be made available to application traffic immediately, regardless of how large the replication backlog is, or alternatively access to it can be restricted until the backlog has been applied.

With the first approach, the group takes the minimum time possible to secure a stable group membership after a primary failure by electing a new primary and then allowing data access immediately while it is still applying any possible backlog from the old primary. Write consistency is ensured, but reads can temporarily retrieve stale data while the new primary applies the backlog. For example, if client C1 wrote `A=2 WHERE A=1` on the old primary just before its failure, when client C1 is reconnected to the new primary it could potentially read `A=1` until the new primary applies its backlog and catches up with the state of the old primary before it left the group.

With the second alternative, the system secures a stable group membership after the primary failure and elects a new primary in the same way as the first alternative, but in this case the group then waits until the new primary applies all backlog and only then does it permit data access. This ensures that in a situation as described previously, when client C1 is reconnected to the new primary it reads `A=2`. However, the trade-off is that the time required to failover is then proportional to the size of the backlog, which on a correctly configured group should be small .

Prior to MySQL 8.0.14 there was no way to configure the failover policy, by default availability was maximized as described in the first approach. In a group with members running MySQL 8.0.14 and later, you can configure the level of transaction consistency guarantees provided by members during primary failover using the `group_replication_consistency` variable. See Impact of Consistency on Primary Election.

Data Flow Operations

Data flow is relevant to group consistency guarantees due to the reads and writes executed against a group, especially when these operations are distributed across all members. Data flow operations apply to both modes of Group Replication: single-primary and multi-primary, however to make this explanation clearer it is restricted to single-primary mode. The usual way to split incoming read or write transactions across a single-primary group's members is to route writes to the primary and evenly distribute reads to the secondaries. Since the group should behave as a single entity, it is reasonable to expect that writes on the primary are instantaneously available on the secondaries. Although Group Replication is written using Group Communication System (GCS) protocols that implement the Paxos algorithm, some parts of Group Replication are asynchronous, which implies that data is asynchronously applied to secondaries. This means that a client C2 can write `B=2 WHERE B=1` on the primary, immediately connect to a secondary and read `B=1`. This is because the secondary is still applying backlog, and has not applied the transaction which was applied by the primary.

Transaction Synchronization Points

You configure a group's consistency guarantee based on the point at which you want to synchronize transactions across the group. To help you understand the concept, this section simplifies the points of synchronizing transactions across a group to be at the time of a read operation or at the time of a write operation. If data is synchronized at the time of a read, the current client session waits until a given point, which is the point in time that all preceding update transactions have been applied, before it can start executing. With this approach, only this session is affected, all other concurrent data operations are not affected.

If data is synchronized at the time of write, the writing session waits until all secondaries have written their data. Group Replication uses a total order on writes, and therefore this implies waiting for this and all preceding writes that are in secondaries' queues to be applied. Therefore when using this synchronization point, the writing session waits for all secondaries queues to be applied.

Any alternative ensures that in the situation described for client C2 would always read `B=2` even if immediately connected to a secondary. Each alternative has its advantages and disadvantages, which are directly related to your system workload. The following examples describe different types of workloads and advise which point of synchronization is appropriate.

Imagine the following situations:

- you want to load balance your reads without deploying additional restrictions on which server you read from to avoid reading stale data, group writes are much less common than group reads.
- you have a group that has a predominantly read-only data, you want read-write transactions to be applied everywhere once they commit, so that subsequent reads are done on up-to-date data that includes the latest write. This ensures that you do not pay the synchronization cost for every RO transaction, but only on RW ones.

In these cases, you should choose to synchronize on writes.

Imagine the following situations:

- you want to load balance your reads without deploying additional restrictions on which server you read from to avoid reading stale data, group writes are much more common than group reads.
- you want specific transactions in your workload to always read up-to-date data from the group, for example whenever sensitive data is updated (such as credentials for a file or similar data) and you want to enforce that reads retrieve the most up to date value.

In these cases, you should choose to synchronize on reads.

18.4.3.2 Configuring Transaction Consistency Guarantees

Although the Transaction Synchronization Points section explains that conceptually there are two synchronization points from which you can choose: on read or on write, these terms were a simplification and the terms used in Group Replication are: *before* and *after* transaction execution. The consistency level can have a different impact on read-only (RO) and read-write (RW) transactions processed by the group as demonstrated in this section.

- How to Choose a Consistency Level
- Impacts of Consistency Levels
- Impact of Consistency on Primary Election

The following list shows the possible consistency levels that you can configure in Group Replication using the `group_replication_consistency` variable, in order of increasing transaction consistency guarantee:

- `EVENTUAL`

Both RO and RW transactions do not wait for preceding transactions to be applied before executing. This was the behavior of Group Replication before the `group_replication_consistency` variable was added. A RW transaction does not wait for other members to apply a transaction. This means that a transaction could be externalized on one member before the others. This also means that in the event of a primary failover, the new primary can accept new RO and RW transactions before the previous primary transactions are all applied. RO transactions could result in outdated values, RW transactions could result in a rollback due to conflicts.

- `BEFORE_ON_PRIMARY_FAILOVER`

  New RO or RW transactions with a newly elected primary that is applying backlog from the old primary are held (not applied) until any backlog has been applied. This ensures that when a primary failover happens, intentionally or not, clients always see the latest value on the primary. This guarantees consistency, but means that clients must be able to handle the delay in the event that a backlog is being applied. Usually this delay should be minimal, but it does depend on the size of the backlog.

- `BEFORE`

  A RW transaction waits for all preceding transactions to complete before being applied. A RO transaction waits for all preceding transactions to complete before being executed. This ensures that this transaction reads the latest value by only affecting the latency of the transaction. This reduces the overhead of synchronization on every RW transaction, by ensuring synchronization is used only on RO transactions. This consistency level also includes the consistency guarantees provided by `BEFORE_ON_PRIMARY_FAILOVER`.

- `AFTER`

  A RW transaction waits until its changes have been applied to all of the other members. This value has no effect on RO transactions. This mode ensures that when a transaction is committed on the local member, any subsequent transaction reads the written value or a more recent value on any group member. Use this mode with a group that is used for predominantly RO operations to ensure that applied RW transactions are applied everywhere once they commit. This could be used by your application to ensure that subsequent reads fetch the latest data which includes the latest writes. This reduces the overhead of synchronization on every RO transaction, by ensuring synchronization is used only on RW transactions. This consistency level also includes the consistency guarantees provided by `BEFORE_ON_PRIMARY_FAILOVER`.

- `BEFORE_AND_AFTER`

  A RW transaction waits for 1) all preceding transactions to complete before being applied and 2) until its changes have been applied on other members. A RO transaction waits for all preceding transactions to complete before execution takes place. This consistency level also includes the consistency guarantees provided by `BEFORE_ON_PRIMARY_FAILOVER`.

The `BEFORE` and `BEFORE_AND_AFTER` consistency levels can be both used on RO and RW transactions. The `AFTER` consistency level has no impact on RO transactions, because they do not generate changes.

How to Choose a Consistency Level

The different consistency levels provide flexibility to both DBAs, who can use them to set up their infrastructure; and to developers who can use the consistency level that best suits their application's requirements. The following scenarios show how to choose a consistency guarantee level based on how you use your group:

- *Scenario 1* you want to load balance your reads without worrying about stale reads, your group write operations are considerably fewer than your group read operations. In this case, you should choose `AFTER`.

- *Scenario 2* you have a data set that applies a lot of writes and you want to do occasional reads without having to worry about reading stale data. In this case, you should choose `BEFORE`.
- *Scenario 3* you want specific transactions in your workload to always read up-to-date data from the group, so that whenever that sensitive data is updated (such as credentials for a file or similar data) you want to enforce that reads always read the most up to date value. In this case, you should choose `BEFORE`.
- *Scenario 4* you have a group that has predominantly read-only (RO) data, you want your read-write (RW) transactions to be applied everywhere once they commit, so that subsequent reads are done on up-to-date data that includes your latest writes and you do not pay the synchronization on every RO transaction, but only on RW ones. In this case, you should choose `AFTER`.
- *Scenario 5* you have a group that has predominantly read-only data, you want your read-write (RW) transactions to always read up-to-date data from the group and to be applied everywhere once they commit, so that subsequent reads are done on up-to-date data that includes your latest write and you do not pay the synchronization on every read-only (RO) transaction, but only on RW ones. In this case, you should choose `BEFORE_AND_AFTER`.

You have the freedom to choose the scope at which the consistency level is enforced. This is important because consistency levels could have a negative impact on group performance if you set them at a global scope. Therefore you can configure the consistency level of a group by using the `group_replication_consistency` system variable at different scopes.

To enforce the consistency level on the current session, use the session scope:

```
> SET @@SESSION.group_replication_consistency= 'BEFORE';
```

To enforce the consistency level on all sessions, use the global scope:

```
> SET @@GLOBAL.group_replication_consistency= 'BEFORE';
```

The possibility of setting the consistency level on specific sessions enables you to take advantage of scenarios such as:

- *Scenario 6* A given system handles several instructions that do not require a strong consistency level, but one kind of instruction does require strong consistency: managing access permissions to documents;. In this scenario, the system changes access permissions and it wants to be sure that all clients see the correct permission. You only need to `SET @@SESSION.group_replication_consistency= 'AFTER'`, on those instructions and leave the other instructions to run with `EVENTUAL` set at the global scope.
- *Scenario 7* On the same system as described in Scenario 6, every day an instruction needs to do some analytical processing, and as such it requires to always read the most up-to-date data. To achieve this, you only need to `SET @@SESSION.group_replication_consistency= 'BEFORE'` on that specific instruction.

To summarize, you do not need to run all transactions with a specific consistency level, especially if only some transactions actually require it.

Note that all read-write transactions are totally ordered in Group Replication, so even when you set the consistency level to `AFTER` for the current session this transaction waits until its changes are applied on all members, which means waiting for this and all preceding transactions that could be in the secondaries' queues. In practice, the consistency level `AFTER` waits for everything until and including this transaction.

Impacts of Consistency Levels

Another way to classify the consistency levels is in terms of impact on the group, that is, the repercussions that the consistency levels have on the other members.

The BEFORE consistency level, apart from being ordered on the transaction stream, only impacts on the local member. That is, it does not require coordination with the other members and does not have repercussions on their transactions. In other words, BEFORE only impacts the transactions on which it is used.

The AFTER and BEFORE_AND_AFTER consistency levels do have side-effects on concurrent transactions executed on other members. These consistency levels make the other members transactions wait if transactions with the EVENTUAL consistency level start while a transaction with AFTER or BEFORE_AND_AFTER is executing. The other members wait until the AFTER transaction is committed on that member, even if the other member's transactions have the EVENTUAL consistency level. In other words, AFTER and BEFORE_AND_AFTER impact *all* ONLINE group members.

To illustrate this further, imagine a group with 3 members, M1, M2 and M3. On member M1 a client issues:

```
> SET @@SESSION.group_replication_consistency= AFTER;
> BEGIN;
> INSERT INTO t1 VALUES (1);
> COMMIT;
```

Then, while the above transaction is being applied, on member M2 a client issues:

```
> SET SESSION group_replication_consistency= EVENTUAL;
```

In this situation, even though the second transaction's consistency level is EVENTUAL, because it starts executing while the first transaction is already in the commit phase on M2, the second transaction has to wait for the first transaction to finish the commit and only then can it execute.

You can only use the consistency levels BEFORE, AFTER and BEFORE_AND_AFTER on ONLINE members, attempting to use them on members in other states causes a session error.

Transactions whose consistency level is not EVENTUAL hold execution until a timeout, configured by wait_timeout value is reached, which defaults to 8 hours. If the timeout is reached an ER_GR_HOLD_WAIT_TIMEOUT error is thrown.

Impact of Consistency on Primary Election

This section describes how a group's consistency level impacts on a single-primary group that has elected a new primary. Such a group automatically detects failures and adjusts the view of the members that are active, in other words the membership configuration. Furthermore, if a group is deployed in single-primary mode, whenever the group's membership changes there is a check performed to detect if there is still a primary member in the group. If there is none, a new one is selected from the list of secondary members. Typically, this is known as the secondary promotion.

Given the fact that the system detects failures and reconfigures itself automatically, the user may also expect that once the promotion takes place, the new primary is in the exact state, data-wise, as that of the old one. In other words, the user may expect that there is no backlog of replicated transactions to be applied on the new primary once he is able to read from and write to it. In practical terms, the user may expect that once his application fails-over to the new primary, there would be no chance, even if temporarily, to read old data or write into old data records.

When flow control is activated and properly tuned on a group, there is only a small chance of transiently reading stale data from a newly elected primary immediately after the promotion, as there should not be a backlog, or if there is one it should be small. Moreover, you might have a proxy or middleware layers that govern application accesses to the primary after a promotion and enforce the consistency criteria at that level. If your group members are using MySQL 8.0.14 or later, you can specify the behavior of the new primary once it is promoted using the group_replication_consistency variable, which controls whether a newly elected primary blocks both reads and writes until after the backlog is fully applied or if it behaves in the manner of

members running MySQL 8.0.13 or earlier. If the `group_replication_consistency` option was set to `BEFORE_ON_PRIMARY_FAILOVER` on a newly elected primary which has backlog to apply, and transactions are issued against the new primary while it is still applying the backlog, incoming transactions are blocked until the backlog is fully applied. Thus, the following anomalies are prevented:

- No stale reads for read-only and read-write transactions. This prevents stale reads from being externalized to the application by the new primary.
- No spurious roll backs for read-write transactions, due to write-write conflicts with replicated read-write transactions still in the backlog waiting to be applied.
- No read skew on read-write transactions, such as:

```
> BEGIN;
> SELECT x FROM t1; -- x=1 because x=2 is in the backlog;
> INSERT x INTO t2;
> COMMIT;
```

  This query should not cause a conflict but writes outdated values.

To summarize, when `group_replication_consistency` is set to `BEFORE_ON_PRIMARY_FAILOVER` you are choosing to prioritize consistency over availability, because reads and writes are held whenever a new primary is elected. This is the trade-off you have to consider when configuring your group. It should also be remembered that if flow control is working correctly, backlog should be minimal. Note that the higher consistency levels `BEFORE`, `AFTER`, and `BEFORE_AND_AFTER` also include the consistency guarantees provided by `BEFORE_ON_PRIMARY_FAILOVER`.

To guarantee that the group provides the same consistency level regardless of which member is promoted to primary, all members of the group should have `BEFORE_ON_PRIMARY_FAILOVER` (or a higher consistency level) persisted to their configuration. For example on each member issue:

```
> SET PERSIST group_replication_consistency='BEFORE_ON_PRIMARY_FAILOVER';
```

This ensures that the members all behave in the same way, and that the configuration is persisted after a restart of the member.

Although all writes are held when using `BEFORE_ON_PRIMARY_FAILOVER` consistency level, not all reads are blocked to ensure that you can still inspect the server while it is applying backlog after a promotion took place. This is useful for debugging, monitoring, observability and troubleshooting. Some queries that do not modify data are allowed, such as the following:

- `SHOW` statements
- `SET` statements
- `DO` statements
- `EMPTY` statements
- `USE` statements
- using `SELECT` statements against the `performance_schema` and `sys` databases
- using `SELECT` statements against the `PROCESSLIST` table from the `infoschema` database
- `SELECT` statements that do not use tables or user defined functions
- `STOP GROUP_REPLICATION` statements
- `SHUTDOWN` statements

- `RESET PERSIST` statements

A transaction cannot be on-hold forever, and if the time held exceeds `wait_timeout` it returns an `ER_GR_HOLD_WAIT_TIMEOUT` error.

18.4.4 Tuning Recovery

Whenever a new member joins a replication group, it connects to a suitable donor and fetches the data that it has missed up until the point it is declared online. This critical component in Group Replication is fault tolerant and configurable. The following section explains how recovery works and how to tune the settings

Donor Selection

A random donor is selected from the existing online members in the group. This way there is a good chance that the same server is not selected more than once when multiple members enter the group.

If the connection to the selected donor fails, a new connection is automatically attempted to a new candidate donor. Once the connection retry limit is reached the recovery procedure terminates with an error.

Note

A donor is picked randomly from the list of online members in the current view.

Enhanced Automatic Donor Switchover

The other main point of concern in recovery as a whole is to make sure that it copes with failures. Hence, Group Replication provides robust error detection mechanisms. In earlier versions of Group Replication, when reaching out to a donor, recovery could only detect connection errors due to authentication issues or some other problem. The reaction to such problematic scenarios was to switch over to a new donor thus a new connection attempt was made to a different member.

This behavior was extended to also cover other failure scenarios:

- *Purged data scenarios* - If the selected donor contains some purged data that is needed for the recovery process then an error occurs. Recovery detects this error and a new donor is selected.
- *Duplicated data* - If a server joining the group already contains some data that conflicts with the data coming from the selected donor during recovery then an error occurs. This could be caused by some errant transactions present in the server joining the group.

  One could argue that recovery should fail instead of switching over to another donor, but in heterogeneous groups there is chance that other members share the conflicting transactions and others do not. For that reason, upon error, recovery selects another donor from the group.
- *Other errors* - If any of the recovery threads fail (receiver or applier threads fail) then an error occurs and recovery switches over to a new donor.

Note

In case of some persistent failures or even transient failures recovery automatically retries connecting to the same or a new donor.

Donor Connection Retries

The recovery data transfer relies on the binary log and existing MySQL replication framework, therefore it is possible that some transient errors could cause errors in the receiver or applier threads. In such cases, the donor switch over process has retry functionality, similar to that found in regular replication.

Number of Attempts

The number of attempts a server joining the group makes when trying to connect to a donor from the pool of donors is 10. This is configured through the `group_replication_recovery_retry_count` plugin variable . The following command sets the maximum number of attempts to connect to a donor to 10.

```
mysql> SET GLOBAL group_replication_recovery_retry_count= 10;
```

Note that this accounts for the global number of attempts that the server joining the group makes connecting to each one of the suitable donors.

Sleep Routines

The `group_replication_recovery_reconnect_interval` plugin variable defines how much time the recovery process should sleep between donor connection attempts. This variable has its default set to 60 seconds and you can change this value dynamically. The following command sets the recovery donor connection retry interval to 120 seconds.

```
mysql> SET GLOBAL group_replication_recovery_reconnect_interval= 120;
```

Note, however, that recovery does not sleep after every donor connection attempt. As the server joining the group is connecting to different servers and not to the same one over and over again, it can assume that the problem that affects server A does not affect server B. As such, recovery suspends only when it has gone through all the possible donors. Once the server joining the group has tried to connect to all the suitable donors in the group and none remains, the recovery process sleeps for the number of seconds configured by the `group_replication_recovery_reconnect_interval` variable.

18.4.5 Network Partitioning

The group needs to achieve consensus whenever a change that needs to be replicated happens. This is the case for regular transactions but is also required for group membership changes and some internal messaging that keeps the group consistent. Consensus requires a majority of group members to agree on a given decision. When a majority of group members is lost, the group is unable to progress and blocks because it cannot secure majority or quorum.

Quorum may be lost when there are multiple involuntary failures, causing a majority of servers to be removed abruptly from the group. For example in a group of 5 servers, if 3 of them become silent at once, the majority is compromised and thus no quorum can be achieved. In fact, the remaining two are not able to tell if the other 3 servers have crashed or whether a network partition has isolated these 2 alone and therefore the group cannot be reconfigured automatically.

On the other hand, if servers exit the group voluntarily, they instruct the group that it should reconfigure itself. In practice, this means that a server that is leaving tells others that it is going away. This means that other members can reconfigure the group properly, the consistency of the membership is maintained and the majority is recalculated. For example, in the above scenario of 5 servers where 3 leave at once, if the 3 leaving servers warn the group that they are leaving, one by one, then the membership is able to adjust itself from 5 to 2, and at the same time, securing quorum while that happens.

Note

Loss of quorum is by itself a side-effect of bad planning. Plan the group size for the number of expected failures (regardless whether they are consecutive, happen all at once or are sporadic).

The following sections explain what to do if the system partitions in such a way that no quorum is automatically achieved by the servers in the group.

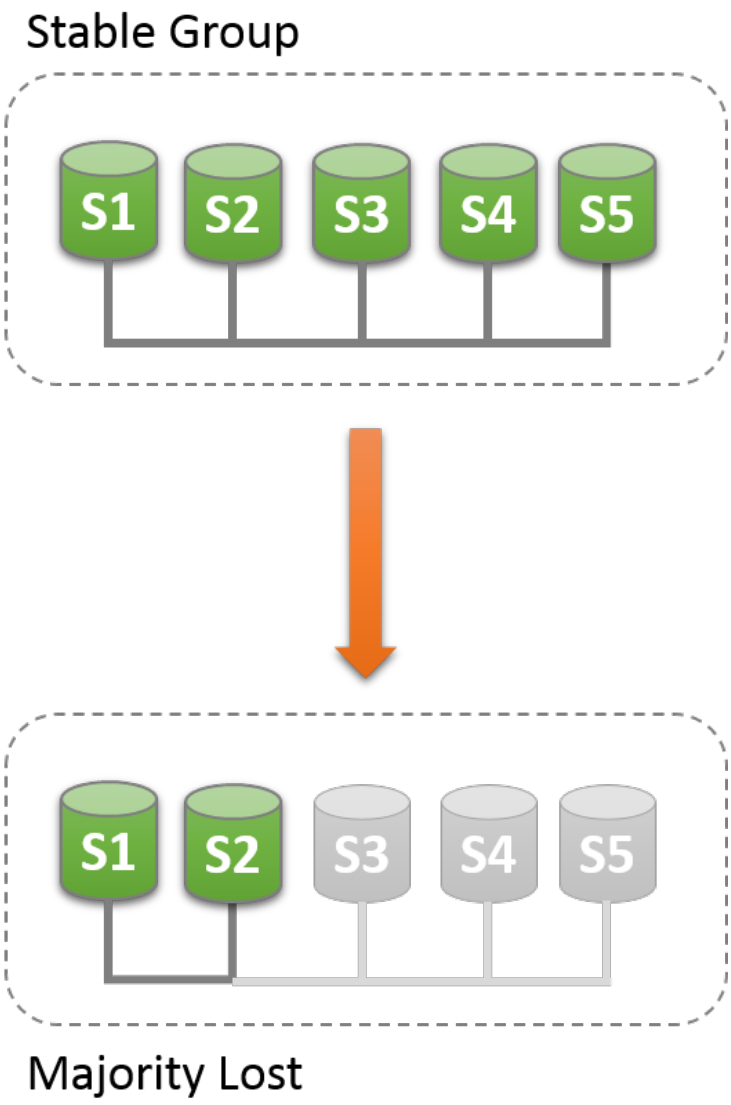
Tip

A primary that has been excluded from a group after a majority loss followed by a reconfiguration can contain extra transactions that are not included in the new group. If this happens, the attempt to add back the excluded member from the group results in an error with the message `This member has more executed transactions than those present in the group.`

Detecting Partitions

The `replication_group_members` performance schema table presents the status of each server in the current view from the perspective of this server. The majority of the time the system does not run into partitioning, and therefore the table shows information that is consistent across all servers in the group. In other words, the status of each server on this table is agreed by all in the current view. However, if there is network partitioning, and quorum is lost, then the table shows the status `UNREACHABLE` for those servers that it cannot contact. This information is exported by the local failure detector built into Group Replication.

Figure 18.7 Losing Quorum



To understand this type of network partition the following section describes a scenario where there are initially 5 servers working together correctly, and the changes that then happen to the group once only 2 servers are online. The scenario is depicted in the figure.

As such, lets assume that there is a group with these 5 servers in it:

- Server s1 with member identifier `199b2df7-4aaf-11e6-bb16-28b2bd168d07`
- Server s2 with member identifier `199bb88e-4aaf-11e6-babe-28b2bd168d07`
- Server s3 with member identifier `1999b9fb-4aaf-11e6-bb54-28b2bd168d07`
- Server s4 with member identifier `19ab72fc-4aaf-11e6-bb51-28b2bd168d07`
- Server s5 with member identifier `19b33846-4aaf-11e6-ba81-28b2bd168d07`

Initially the group is running fine and the servers are happily communicating with each other. You can verify this by logging into s1 and looking at its `replication_group_members` performance schema table. For example:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+---------------------------+--------------------------------------+-------------+-------------+-----------
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_STA
+---------------------------+--------------------------------------+-------------+-------------+-----------
| group_replication_applier | 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | 127.0.0.1   |       13002 | ONLINE
| group_replication_applier | 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | 127.0.0.1   |       13001 | ONLINE
| group_replication_applier | 199bb88e-4aaf-11e6-babe-28b2bd168d07 | 127.0.0.1   |       13000 | ONLINE
| group_replication_applier | 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | 127.0.0.1   |       13003 | ONLINE
| group_replication_applier | 19b33846-4aaf-11e6-ba81-28b2bd168d07 | 127.0.0.1   |       13004 | ONLINE
+---------------------------+--------------------------------------+-------------+-------------+-----------
```

However, moments later there is a catastrophic failure and servers s3, s4 and s5 stop unexpectedly. A few seconds after this, looking again at the `replication_group_members` table on s1 shows that it is still online, but several others members are not. In fact, as seen below they are marked as `UNREACHABLE`. Moreover, the system could not reconfigure itself to change the membership, because the majority has been lost.

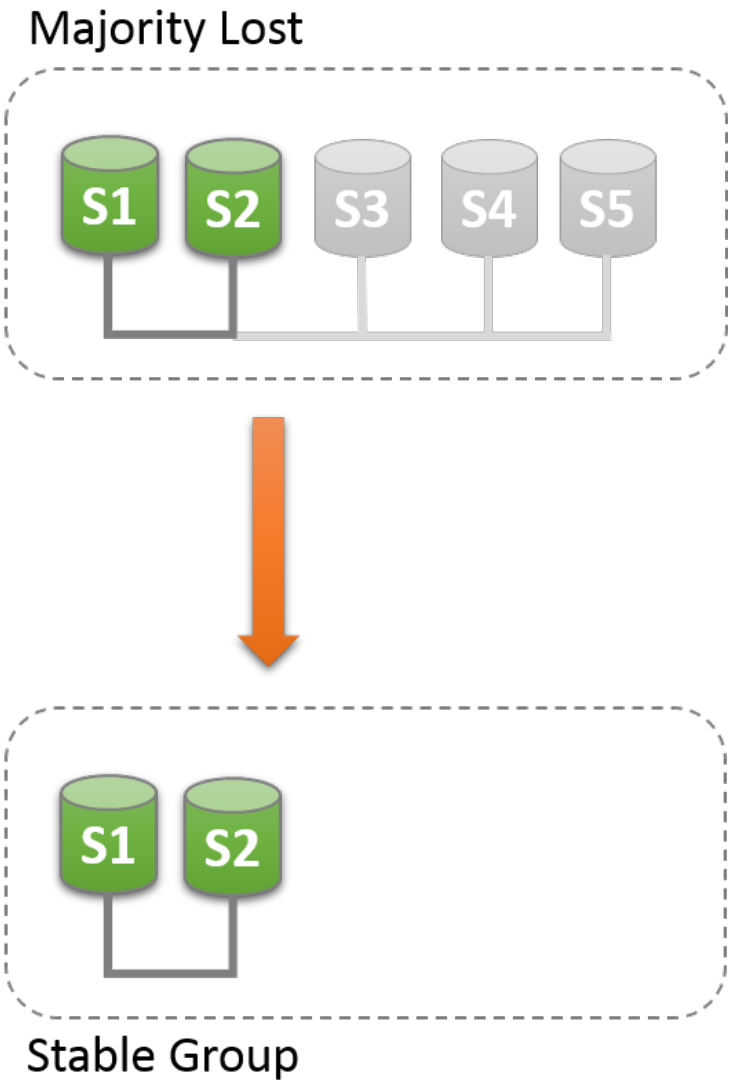
```
mysql> SELECT * FROM performance_schema.replication_group_members;
+---------------------------+--------------------------------------+-------------+-------------+-----------
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_STA
+---------------------------+--------------------------------------+-------------+-------------+-----------
| group_replication_applier | 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | 127.0.0.1   |       13002 | UNREACHABL
| group_replication_applier | 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | 127.0.0.1   |       13001 | ONLINE
| group_replication_applier | 199bb88e-4aaf-11e6-babe-28b2bd168d07 | 127.0.0.1   |       13000 | ONLINE
| group_replication_applier | 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | 127.0.0.1   |       13003 | UNREACHABL
| group_replication_applier | 19b33846-4aaf-11e6-ba81-28b2bd168d07 | 127.0.0.1   |       13004 | UNREACHABL
+---------------------------+--------------------------------------+-------------+-------------+-----------
```

The table shows that s1 is now in a group that has no means of progressing without external intervention, because a majority of the servers are unreachable. In this particular case, the group membership list needs to be reset to allow the system to proceed, which is explained in this section. Alternatively, you could also choose to stop Group Replication on s1 and s2 (or stop completely s1 and s2), figure out what happened with s3, s4 and s5 and then restart Group Replication (or the servers).

Unblocking a Partition

Group replication enables you to reset the group membership list by forcing a specific configuration. For instance in the case above, where s1 and s2 are the only servers online, you could chose to force a membership configuration consisting of only s1 and s2. This requires checking some information about s1 and s2 and then using the `group_replication_force_members` variable.

Figure 18.8 Forcing a New Membership



Suppose that you are back in the situation where s1 and s2 are the only servers left in the group. Servers s3, s4 and s5 have left the group unexpectedly. To make servers s1 and s2 continue, you want to force a membership configuration that contains only s1 and s2.

Warning

This procedure uses `group_replication_force_members` and should be considered a last resort remedy. It *must* be used with extreme care and only for overriding loss of quorum. If misused, it could create an artificial split-brain scenario or block the entire system altogether.

Recall that the system is blocked and the current configuration is the following (as perceived by the local failure detector on s1):

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+---------------------------+--------------------------------------+-------------+-------------+-------
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER
+---------------------------+--------------------------------------+-------------+-------------+-------
| group_replication_applier | 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | 127.0.0.1   |       13002 | UNREAC
| group_replication_applier | 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | 127.0.0.1   |       13001 | ONLINE
| group_replication_applier | 199bb88e-4aaf-11e6-babe-28b2bd168d07 | 127.0.0.1   |       13000 | ONLINE
```

```
| group_replication_applier | 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | 127.0.0.1    |       13003 | UNREACHABL
| group_replication_applier | 19b33846-4aaf-11e6-ba81-28b2bd168d07 | 127.0.0.1    |       13004 | UNREACHABL
+---------------------------+--------------------------------------+--------------+-------------+-----------
```

The first thing to do is to check what is the peer address (group communication identifier) for s1 and s2. Log in to s1 and s2 and get that information as follows.

```
mysql> SELECT @@group_replication_local_address;
+-----------------------------------+
| @@group_replication_local_address |
+-----------------------------------+
| 127.0.0.1:10000                   |
+-----------------------------------+
```

Then log in to s2 and do the same thing:

```
mysql> SELECT @@group_replication_local_address;
+-----------------------------------+
| @@group_replication_local_address |
+-----------------------------------+
| 127.0.0.1:10001                   |
+-----------------------------------+
```

Once you know the group communication addresses of s1 (`127.0.0.1:10000`) and s2 (`127.0.0.1:10001`), you can use that on one of the two servers to inject a new membership configuration, thus overriding the existing one that has lost quorum. To do that on s1:

```
mysql> SET GLOBAL group_replication_force_members="127.0.0.1:10000,127.0.0.1:10001";
```

This unblocks the group by forcing a different configuration. Check `replication_group_members` on both s1 and s2 to verify the group membership after this change. First on s1.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+---------------------------+--------------------------------------+-------------+-------------+-----------
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_STA
+---------------------------+--------------------------------------+-------------+-------------+-----------
| group_replication_applier | b5ffe505-4ab6-11e6-b04b-28b2bd168d07 | 127.0.0.1   |       13000 | ONLINE
| group_replication_applier | b60907e7-4ab6-11e6-afb7-28b2bd168d07 | 127.0.0.1   |       13001 | ONLINE
+---------------------------+--------------------------------------+-------------+-------------+-----------
```

And then on s2.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+---------------------------+--------------------------------------+-------------+-------------+-----------
| CHANNEL_NAME              | MEMBER_ID                            | MEMBER_HOST | MEMBER_PORT | MEMBER_STA
+---------------------------+--------------------------------------+-------------+-------------+-----------
| group_replication_applier | b5ffe505-4ab6-11e6-b04b-28b2bd168d07 | 127.0.0.1   |       13000 | ONLINE
| group_replication_applier | b60907e7-4ab6-11e6-afb7-28b2bd168d07 | 127.0.0.1   |       13001 | ONLINE
+---------------------------+--------------------------------------+-------------+-------------+-----------
```

When forcing a new membership configuration, make sure that any servers are going to be forced out of the group are indeed stopped. In the scenario depicted above, if s3, s4 and s5 are not really unreachable but instead are online, they may have formed their own functional partition (they are 3 out of 5, hence they have the majority). In that case, forcing a group membership list with s1 and s2 could create an artificial split-brain situation. Therefore it is important before forcing a new membership configuration to ensure that the servers to be excluded are indeed shutdown and if they are not, shut them down before proceeding.

After you have used the `group_replication_force_members` system variable to successfully force a new group membership and unblock the group, ensure that you clear the system variable. `group_replication_force_members` must be empty in order to issue a `START GROUP_REPLICATION` statement.

18.4.6 Support For IPv6 And For Mixed IPv6 And IPv4 Groups

From MySQL 8.0.14, Group Replication group members can use IPv6 addresses as an alternative to IPv4 addresses for communications within the group. To use IPv6 addresses, the operating system on the server host and the MySQL Server instance must both be configured to support IPv6. For instructions to set up IPv6 support for a server instance, see Section 5.1.12, "IPv6 Support".

IPv6 addresses, or host names that resolve to them, can be specified as the network address that the member provides in the `group_replication_local_address` option for connections from other members. When specified with a port number, an IPv6 address must be specified in square brackets, for example:

```
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

The network address or host name specified in `group_replication_local_address` is used by Group Replication as the unique identifier for a group member within the replication group. If a host name specified as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. The address or host name specified as the Group Replication local address is not the same as the MySQL server SQL protocol host and port, and is not specified in the `bind_address` system variable for the server instance. For the purpose of IP address whitelisting for Group Replication (see Section 18.5.1, "IP Address Whitelisting"), the address that you specify for each group member in `group_replication_local_address` must be added to the list for the `group_replication_ip_whitelist` option on the other servers in the replication group.

A replication group can contain a combination of members that present an IPv6 address as their Group Replication local address, and members that present an IPv4 address. When a server joins such a mixed group, it must make the initial contact with the seed member using the protocol that the seed member advertises in the `group_replication_group_seeds` option, whether that is IPv4 or IPv6. If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 Group Replication local address, or the reverse, you must also set up and whitelist an alternative address for the joining member for the required protocol (or a host name that resolves to an address for that protocol). If a joining member does not have a whitelisted address for the appropriate protocol, its connection attempt is refused. The alternative address or host name only needs to be added to the `group_replication_ip_whitelist` option on the other servers in the replication group, not to the `group_replication_local_address` value for the joining member (which can only contain a single address).

For example, server A is a seed member for a group, and has the following configuration settings for Group Replication, so that it is advertising an IPv6 address in the `group_replication_group_seeds` option:

```
group_replication_bootstrap_group=on
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
group_replication_group_seeds= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

Server B is a joining member for the group, and has the following configuration settings for Group Replication, so that it has an IPv4 Group Replication local address:

```
group_replication_bootstrap_group=off
group_replication_local_address= "203.0.113.21:33061"
group_replication_group_seeds= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

Server B also has an alternative IPv6 address `2001:db8:8b0:40:3d9c:cc43:e006:19e8`. For Server B to join the group successfully, both its IPv4 Group Replication local address, and its alternative IPv6 address, must be listed in Server A's whitelist, as in the following example:

```
group replication_ip_whitelist=
"203.0.113.0/24,2001:db8:85a3:8d3:1319:8a2e:370:7348,
2001:db8:8b0:40:3d9c:cc43:e006:19e8"
```

As a best practice for Group Replication IP whitelisting, Server B (and all other group members) should have the same whitelist as Server A, unless security requirements demand otherwise.

If any or all members of a replication group are using an older MySQL Server version that does not support the use of IPv6 addresses for Group Replication, a member cannot participate in the group using an IPv6 address (or a host name that resolves to one) as its Group Replication local address. This applies both in the case where at least one existing member uses an IPv6 address and a new member that does not support this attempts to join, and in the case where a new member attempts to join using an IPv6 address but the group includes at least one member that does not support this. In each situation, the new member cannot join. To make a joining member present an IPv4 address for group communications, you can either change the value of `group_replication_local_address` to an IPv4 address, or configure your DNS to resolve the joining member's existing host name to an IPv4 address. After you have upgraded every group member to a MySQL Server version that supports IPv6 for Group Replication, you can change the `group_replication_local_address` value for each member to an IPv6 address, or configure your DNS to present an IPv6 address. Changing the value of `group_replication_local_address` takes effect only when you stop and restart Group Replication.

18.4.7 Using MySQL Enterprise Backup with Group Replication

MySQL Enterprise Backup is a commercially-licensed backup utility for MySQL Server, available with MySQL Enterprise Edition. This section explains how to back up and subsequently restore a Group Replication member using MySQL Enterprise Backup. The same technique can be used to quickly add a new member to a group.

Backing up a Group Replication Member Using MySQL Enterprise Backup

Backing up a Group Replication member is similar to backing up a stand-alone MySQL instance. The following instructions assume that you are already familiar with how to use MySQL Enterprise Backup to perform a backup; if that is not the case, please review the MySQL Enterprise Backup 8.0 User's Guide, especially Backing Up a Database Server. Also note the requirements described in Grant MySQL Privileges to Backup Administrator and Using MySQL Enterprise Backup with Group Replication.

Consider the following group with three members, `s1`, `s2`, and `s3`, running on hosts with the same names:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-------------+-------------+--------------+
| member_host | member_port | member_state |
+-------------+-------------+--------------+
| s1          |        3306 | ONLINE       |
| s2          |        3306 | ONLINE       |
| s3          |        3306 | ONLINE       |
+-------------+-------------+--------------+
```

Using MySQL Enterprise Backup, create a backup of `s2` by issuing on its host, for example, the following command:

```
s2> mysqlbackup --defaults-file=/etc/my.cnf --backup-image=/backups/my.mbi_`date +%d%m_%H%M` \
        --backup-dir=/backups/backup_`date +%d%m_%H%M` --user=root -p \
        --host=127.0.0.1 backup-to-image
```

Notes

- If the system variable `sql_require_primary_key` is set to `ON` for the group, MySQL Enterprise Backup will not be able to log the backup progress on the servers. This is because the `backup_progress` table on the server is a CSV table, for which primary keys are not supported. In that case, `mysqlbackup` issues the following warnings during the backup operation:

  ```
  181011 11:17:06 MAIN WARNING: MySQL query 'CREATE TABLE IF NOT EXISTS
  ```

```
mysql.backup_progress( `backup_id` BIGINT NOT NULL, `tool_name` VARCHAR(4096)
NOT NULL, `error_code` INT NOT NULL, `error_message` VARCHAR(4096) NOT NULL,
`current_time` TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP              ON
UPDATE CURRENT_TIMESTAMP,`current_state` VARCHAR(200) NOT NULL ) ENGINE=CSV
DEFAULT CHARSET=utf8 COLLATE=utf8_bin': 3750, Unable to create a table
without PK, when system variable 'sql_require_primary_key' is set. Add a PK
to the table or unset this variable to avoid this message. Note that tables
without PK can cause performance problems in row-based replication, so please
consult your DBA before changing this setting.
181011 11:17:06 MAIN WARNING: This backup operation's progress info cannot be
logged.
```

This does not prevent `mysqlbackup` from finishing the backup though.

- *For MySQL Enterprise Backup 8.0.11*, when backing up a secondary member, as MySQL Enterprise Backup cannot write backup status and metadata to a read-only server instance, it issues the following warnings during the backup operation:

  ```
  181113 21:31:08 MAIN WARNING: This backup operation cannot write to backup
  progress. The MySQL server is running with the --super-read-only option.
  ```

  You can avoid the warning by using the `--no-history-logging` option with your backup command. This is not an issue for MySQL Enterprise Backup 8.0.12 and later—see Using MySQL Enterprise Backup with Group Replication for details.

Restoring a Failed Member

Assume one of the members (`s3` in the following example) is irreconcilably corrupted. The most recent backup of group member `s2` can be used to restore `s3`. Here are the steps for performing the restore:

1. *Copy the backup of s2 onto the host for s3.* The exact way to copy the backup depends on the operating system and tools available to you. In this example, we assume the hosts are both Linux servers and use SCP to copy the files between them:

   ```
   s2/backups> scp my.mbi_2206_1429 s3:/backups
   ```

2. *Restore the backup.* Connect to the target host (the host for `s3` in this case), and restore the backup using MySQL Enterprise Backup. Here are the steps:

   a. Stop the corrupted server, if it is still running. For example, on Linux distributions that use systemd:

      ```
      s3> systemctl stop mysqld
      ```

   b. Preserve the two configuration files in the corrupted server's data directory, `auto.cnf` and `mysqld-auto.cnf` (if it exists), by copying them to a safe location outside of the data directory. This is for preserving the server's UUID and Section 5.1.9.3, “Persisted System Variables” (if used), which are needed in the steps below.

   c. Delete all contents in the data directory of `s3`. For example:

      ```
      s3> rm -rf /var/lib/mysql/*
      ```

      If the system variables `innodb_data_home_dir`, `innodb_log_group_home_dir`, and `innodb_undo_directory` point to any directories other than the data directory, they should also be made empty; otherwise, the restore operation will fail.

   d. Restore backup of `s2` onto the host for `s3`:

      ```
      s3> mysqlbackup --defaults-file=/etc/my.cnf \
        --datadir=/var/lib/mysql \
        --backup-image=/backups/my.mbi_2206_1429  \
        --backup-dir=/tmp/restore_`date +%d%m_%H%M` copy-back-and-apply-log
      ```

Note

The command above assumes that the binary logs and relay logs on `s2` and `s3` have the same base name and are at the same location on the two servers. If these conditions are not met, you should use the `--log-bin` and `--relay-log` options to restore the binary log and relay log to their original file paths on `s3`. For example, if you know that on `s3` the binary log's base name is `s3-bin` and the relay-log's base name is `s3-relay-bin`, your restore command should look like:

```
mysqlbackup --defaults-file=/etc/my.cnf \
  --datadir=/var/lib/mysql \
  --backup-image=/backups/my.mbi_2206_1429  \
  --log-bin=s3-bin --relay-log=s3-relay-bin \
  --backup-dir=/tmp/restore_`date +%d%m_%H%M` copy-back-and-apply-log
```

Being able to restore the binary log and relay log to the right file paths makes the restore process easier; if that is impossible for some reason, see Rebuild the Failed Member to Rejoin as a New Member.

3. *Restore the `auto.cnf` file for s3.* To rejoin the replication group, the restored member *must* have the same `server_uuid` it used to join the group before. Supply the old server UUID by copying the `auto.cnf` file preserved in step 2 above into the data directory of the restored member.

   Note

   If you cannot supply the failed member's original `server_uuid` to the restored member by restoring its old `auto.cnf` file, you will have to let the restored member join the group as a new member; see instructions in Rebuild the Failed Member to Rejoin as a New Member below on how to do that.

4. *Restore the `mysqld-auto.cnf` file for s3 (only required if s3 used persistent system variables).* The settings for the Section 5.1.9.3, “Persisted System Variables” that were used to configure the failed member must be provided to the restored member. These settings are to be found in the `mysqld-auto.cnf` file of the failed server, which you should have preserved in step 2 above. Restore the file to the data directory of the restored server. See Restoring Persisted System Variables on what to do if you do not have a copy of the file.

5. *Start the restored server.* For example, on Linux distributions that use systemd:

   ```
   systemctl start mysqld
   ```

   Note

   If the server you are restoring is a primary member, perform the steps described in Restoring a Primary Member *before starting the restored server*.

6. *Restart Group Replication.* Connect to the restarted `s3` using, for example, a `mysql` client, and issue the following command:

   ```
   mysql> START GROUP_REPLICATION;
   ```

   Before the restored instance can become an online member of the group, it needs to apply any transactions that have happened to the group after the backup was taken; this is achieved using Group Replication's distributed recovery mechanism, and the process starts after the START GROUP_REPLICATION statement has been issued. To check the member status of the restored instance, issue:

   ```
   mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
   ```

```
+-------------+-------------+--------------+
| member_host | member_port | member_state |
+-------------+-------------+--------------+
| s1          |        3306 | ONLINE       |
| s2          |        3306 | ONLINE       |
| s3          |        3306 | RECOVERING   |
+-------------+-------------+--------------+
```

This shows that `s3` is applying transactions to catch up with the group. Once it has caught up with the rest of the group, its `member_state` changes to `ONLINE`:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_membe
+-------------+-------------+--------------+
| member_host | member_port | member_state |
+-------------+-------------+--------------+
| s1          |        3306 | ONLINE       |
| s2          |        3306 | ONLINE       |
| s3          |        3306 | ONLINE       |
+-------------+-------------+--------------+
```

Note

If the server you are restoring is a primary member, once it has gained synchrony with the group and become `ONLINE`, perform the steps described at the end of Restoring a Primary Member to revert the configuration changes you had made to the server before you started it.

The member has now been fully restored from the backup and functions as a regular member of the group.

Rebuild the Failed Member to Rejoin as a New Member

Sometimes, the steps outlined above in Restoring a Failed Member cannot be carried out because, for example, the binary log or relay log is corrupted, or it is just missing from the backup. In such a situation, use the backup to rebuild the member, and then add it to the group as a new member. In the steps below, we assume the rebuilt member will be named `s3`, like the failed member, and it will be run on the same host as `s3` was:

1. *Copy the backup of s2 onto the host for s3 .* The exact way to copy the backup depends on the operating system and tools available to you. In this example we assume the hosts are both Linux servers and use SCP to copy the files between them:

   ```
   s2/backups> scp my.mbi_2206_1429 s3:/backups
   ```

2. *Restore the backup.* Connect to the target host (the host for `s3` in this case), and restore the backup using MySQL Enterprise Backup. Here are the steps:

   a. Stop the corrupted server, if it is still running. For example, on Linux distributions that use systemd:

      ```
      s3> systemctl stop mysqld
      ```

   b. Preserve the configuration file `mysqld-auto.cnf`, if it is found in the corrupted server's data directory, by copying it to a safe location outside of the data directory. This is for preserving the server's Section 5.1.9.3, “Persisted System Variables”, which are needed later.

   c. Delete all contents in the data directory of `s3`. For example:

      ```
      s3> rm -rf /var/lib/mysql/*
      ```

      If the system variables `innodb_data_home_dir`, `innodb_log_group_home_dir`, and `innodb_undo_directory` point to any directories other than the data directory, they should also be made empty; otherwise, the restore operation will fail.

d. Restore the backup of `s2` onto the host of `s3`. With this approach, we are rebuilding `s3` as a new member, for which we do not need or do not want to use the old binary and relay logs in the backup; therefore, if these logs have been included in your backup, exclude them using the `--skip-binlog` and `--skip-relaylog` options:

```
s3> mysqlbackup --defaults-file=/etc/my.cnf \
  --datadir=/var/lib/mysql \
  --backup-image=/backups/my.mbi_2206_1429  \
  --backup-dir=/tmp/restore_`date +%d%m_%H%M` \
  --skip-binlog --skip-relaylog \
  copy-back-and-apply-log
```

Note

If you have healthy binary log and relay logs in the backup that you can transfer onto the target host with no issues, you are recommended to follow the easier procedure as described in Restoring a Failed Member above.

3. *Restore the `mysqld-auto.cnf` file for s3 (only required if s3 used persistent system variables).* The settings for the Section 5.1.9.3, “Persisted System Variables” that were used to configure the failed member must be provided to the restored server. These settings are to be found in the `mysqld-auto.cnf` file of the failed server, which you should have preserved in step 2 above. Restore the file to the data directory of the restored server. See Restoring Persisted System Variables on what to do if you do not have a copy of the file.

Note

Do NOT restore the corrupted server's `auto.cnf` file to the data directory of the new member—when the rebuilt `s3` joins the group as a new member, it is going to be assigned a new server UUID.

4. *Start the restored server.* For example, on Linux distributions that use systemd:

```
systemctl start mysqld
```

Note

If the server you are restoring is a primary member, perform the steps described in Restoring a Primary Member *before starting the restored server*.

5. *Reconfigure the restored member to join Group Replication.* Connect to the restored server with a `mysql` client and reset the master and slave information with the following commands:

```
mysql> RESET MASTER;
```

```
mysql> RESET SLAVE ALL;
```

For the restored server to be able to recover automatically using Group Replication's built-in mechanism for distributed recovery, configure the server's `gtid_executed` variable. To do this, use the `backup_gtid_executed.sql` file included in the backup of `s2`, which is usually restored under the restored member's data directory. Disable binary logging, use the `backup_gtid_executed.sql` file to configure `gtid_executed`, and then re-enable binary logging by issuing the following statements with your `mysql` client:

```
mysql> SET SQL_LOG_BIN=OFF;
mysql> SOURCE datadir/backup_gtid_executed.sql
mysql> SET SQL_LOG_BIN=ON;
```

Then, configure the Group Replication user credentials on the member:

```
mysql> CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='password' /
  FOR CHANNEL 'group_replication_recovery';
```

6. *Restart Group Replication.* Issue the following command to the restored server with your `mysql` client:

```
mysql> START GROUP_REPLICATION;
```

Before the restored instance can become an online member of the group, it needs to apply any transactions that have happened to the group after the backup was taken; this is achieved using Group Replication's distributed recovery mechanism, and the process starts after the START GROUP_REPLICATION statement has been issued. To check the member status of the restored instance, issue:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_membe
+-------------+-------------+--------------+
| member_host | member_port | member_state |
+-------------+-------------+--------------+
| s3          |        3306 | RECOVERING   |
| s2          |        3306 | ONLINE       |
| s1          |        3306 | ONLINE       |
+-------------+-------------+--------------+
```

This shows that `s3` is applying transactions to catch up with the group. Once it has caught up with the rest of the group, its `member_state` changes to `ONLINE`:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_membe
+-------------+-------------+--------------+
| member_host | member_port | member_state |
+-------------+-------------+--------------+
| s3          |        3306 | ONLINE       |
| s2          |        3306 | ONLINE       |
| s1          |        3306 | ONLINE       |
+-------------+-------------+--------------+
```

Note

If the server you are restoring is a primary member, once it has gained synchrony with the group and become `ONLINE`, perform the steps described at the end of Restoring a Primary Member to revert the configuration changes you had made to the server before you started it.

The member has now been restored to the group as a new member.

Restoring Persisted System Variables. `mysqlbackup` does not provide support for backing up or preserving Section 5.1.9.3, “Persisted System Variables”—the file `mysqld-auto.cnf` is not included in a backup. To start the restored member with its persisted variable settings, you need to do one of the following:

- Preserve a copy of the `mysqld-auto.cnf` file from the corrupted server, and copy it to the restored server's data directory.
- Copy the `mysqld-auto.cnf` file from another member of the group replication cluster into the restored server's data directory, if that member has the same persisted system variable settings as the corrupted member.
- After the restored server is started and before you restart group replication, set all the system variables manually to their persisted values through a `mysql` client.

Restoring a Primary Member. If the restored member is a primary in the group, care must be taken to prevent writes to the restored database during the Group Replication recovery phase: Depending on

how the group is accessed by clients, there is a possibility of DML statements being executed on the restored member once it becomes accessible on the network, prior to the member finishing its catch-up on the activities it has missed while off the group. To avoid this, *before starting the restored server*, configure the following system variables in the server option file:

```
group_replication_start_on_boot=OFF
super_read_only=ON
event_scheduler=OFF
```

These settings ensure that the member becomes read-only at startup and that the event scheduler is turned off while the member is catching up with the group during the recovery phase. Adequate error handling must also be configured on the clients, as they will be prevented temporarily from performing DML operations during this period on the restored member. Once the restore process is fully completed and the restored member is in-sync with the rest of the group, revert those changes; restart the event scheduler:

```
mysql> SET global event_scheduler=ON;
```

Edit the following system variables in the member's option file, so things are correctly configured for the next startup:

```
group_replication_start_on_boot=ON
super_read_only=OFF
event_scheduler=ON
```

18.5 Group Replication Security

This section explains how to secure a group, securing the connections between members of a group, or by establishing a security perimeter using address whitelisting.

18.5.1 IP Address Whitelisting

The Group Replication plugin has a configuration option to determine from which hosts an incoming Group Communication System connection can be accepted. This option is called `group_replication_ip_whitelist`. If you set this option on a server s1, then when server s2 is establishing a connection to s1 for the purpose of engaging group communication, s1 first checks the whitelist before accepting the connection from s2. If s2 is in the whitelist, then s1 accepts the connection, otherwise s1 rejects the connection attempt by s2.

If you do not specify a whitelist explicitly, the group communication engine (XCom) automatically scans active interfaces on the host, and identifies those with addresses on private subnetworks. These addresses and the `localhost` IP address for IPv4 and (from MySQL 8.0.14) IPv6 are used to create an automatic Group Replication whitelist. The automatic whitelist therefore includes any IP addresses found for the host in the following ranges:

```
IPv4 (as defined in RFC 1918)
10/8 prefix       (10.0.0.0 - 10.255.255.255) - Class A
172.16/12 prefix  (172.16.0.0 - 172.31.255.255) - Class B
192.168/16 prefix (192.168.0.0 - 192.168.255.255) - Class C

IPv6 (as defined in RFC 4193 and RFC 5156)
fc00:/7 prefix    - unique-local addresses
fe80::/10 prefix  - link-local unicast addresses

127.0.0.1 - localhost for IPv4
::1       - localhost for IPv6
```

An entry is added to the error log stating the addresses that have been whitelisted automatically for the host.

The automatic whitelist of private addresses cannot be used for connections from servers outside the private network, so a server, even if it has interfaces on public IPs, does not by default allow Group Replication connections from external hosts. For Group Replication connections between server instances that are on different machines, you must provide public IP addresses and specify these as an explicit whitelist. If you specify any entries for the whitelist, the private and `localhost` addresses are not added automatically, so if you use any of these, you must specify them explicitly.

To specify a whitelist manually, use the `group_replication_ip_whitelist` option. You cannot change the whitelist on a server while it is an active member of a replication group. If the member is active, you must issue a `STOP GROUP_REPLICATION` statement before changing the whitelist, and a `START GROUP_REPLICATION` statement afterwards.

In the whitelist, you can specify any combination of the following:

- IPv4 addresses (for example, `198.51.100.44`)
- IPv4 addresses with CIDR notation (for example, `192.0.2.21/24`)
- IPv6 addresses, from MySQL 8.0.14 (for example, `2001:db8:85a3:8d3:1319:8a2e:370:7348`)
- IPv6 addresses with CIDR notation, from MySQL 8.0.14 (for example, `2001:db8:85a3:8d3::/64`)
- Host names (for example, `example.org`)
- Host names with CIDR notation (for example, `www.example.com/24`)

Before MySQL 8.0.14, host names could only resolve to IPv4 addresses. From MySQL 8.0.14, host names can resolve to IPv4 addresses, IPv6 addresses, or both. If a host name resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. You can use CIDR notation in combination with host names or IP addresses to whitelist a block of IP addresses with a particular network prefix, but do ensure that all the IP addresses in the specified subnet are under your control.

You must stop and restart Group Replication on a member in order to change its whitelist. A comma must separate each entry in the whitelist. For example:

```
mysql> STOP GROUP_REPLICATION;
mysql> SET GLOBAL group_replication_ip_whitelist="192.0.2.21/24,198.51.100.44,203.0.113.0/24,2001:db8:8
mysql> START GROUP_REPLICATION;
```

The whitelist must contain the IP address or host name that is specified in each member's `group_replication_local_address` system variable. This address is not the same as the MySQL server SQL protocol host and port, and is not specified in the `bind_address` system variable for the server instance. If a host name used as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is preferred for Group Replication connections.

To join a replication group, a server needs to be whitelisted on the seed member to which it makes the request to join the group. Typically, this would be the bootstrap member for the replication group, but it can be any of the servers listed by the `group_replication_group_seeds` option in the configuration for the server joining the group. If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 `group_replication_local_address`, or the reverse, you must also set up and whitelist an alternative address for the joining member for the protocol offered by the seed member (or a host name that resolves to an address for that protocol). This is because when a server joins a replication group, it must make the initial contact with the seed member using the protocol that the seed member advertises in the `group_replication_group_seeds` option, whether that is IPv4 or IPv6. If a joining member does not have a whitelisted address for the appropriate protocol, its connection attempt is refused. For more information on managing mixed IPv4 and IPv6 replication groups, see Section 18.4.6, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”.

When a replication group is reconfigured (for example, when a new primary is elected or a member joins or leaves), the group members re-establish connections between themselves. If a group member is only whitelisted by servers that are no longer part of the replication group after the reconfiguration, it is unable to reconnect to the remaining servers in the replication group that do not whitelist it. To avoid this scenario entirely, specify the same whitelist for all servers that are members of the replication group.

Note

It is possible to configure different whitelists on different group members according to your security requirements, for example, in order to keep different subnets separate. If you need to configure different whitelists to meet your security requirements, ensure that there is sufficient overlap between the whitelists in the replication group to maximize the possibility of servers being able to reconnect in the absence of their original seed member.

For host names, name resolution takes place only when a connection request is made by another server. A host name that cannot be resolved is not considered for whitelist validation, and a warning message is written to the error log. Forward-confirmed reverse DNS (FCrDNS) verification is carried out for resolved host names.

Warning

Host names are inherently less secure than IP addresses in a whitelist. FCrDNS verification provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your whitelist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

18.5.2 Secure Socket Layer Support (SSL)

MySQL Group Replication supports OpenSSL and wolfSSL builds of MySQL Server.

Group communication connections as well as recovery connections, are secured using SSL. The following sections explain how to configure connections.

Configuring SSL for Recovery

Recovery is performed through a regular asynchronous replication connection. Once the donor is selected, the server joining the group establishes an asynchronous replication connection. This is all automatic.

However, a user that requires an SSL connection must have been created before the server joining the group connects to the donor. Typically, this is set up at the time one is provisioning a server to join the group.

```
donor> SET SQL_LOG_BIN=0;
donor> CREATE USER 'rec_ssl_user'@'%' REQUIRE SSL;
donor> GRANT replication slave ON *.* TO 'rec_ssl_user'@'%';
donor> SET SQL_LOG_BIN=1;
```

Assuming that all servers already in the group have a replication user set up to use SSL, you configure the server joining the group to use those credentials when connecting to the donor. That is done according to the values of the SSL options provided for the Group Replication plugin.

```
new_member> SET GLOBAL group_replication_recovery_use_ssl=1;
new_member> SET GLOBAL group_replication_recovery_ssl_ca= '.../cacert.pem';
new_member> SET GLOBAL group_replication_recovery_ssl_cert= '.../client-cert.pem';
new_member> SET GLOBAL group_replication_recovery_ssl_key= '.../client-key.pem';
```

And by configuring the recovery channel to use the credentials of the user that requires an SSL connection.

```
new_member> CHANGE MASTER TO MASTER_USER="rec_ssl_user" FOR CHANNEL "group_replication_recovery";
new_member> START GROUP_REPLICATION;
```

Configuring SSL for Group Communication

Secure sockets can be used to establish communication between members in a group. The configuration for this depends on the server's SSL configuration. As such, if the server has SSL configured, the Group Replication plugin also has SSL configured. For more information on the options for configuring the server SSL, see Section 6.4.2, “Command Options for Encrypted Connections”. The options which configure Group Replication are shown in the following table.

Table 18.3 SSL Options

Plugin Configuration	Description
ssl_key	Path of key file. To be used as client and server certificate.
ssl_cert	Path of certificate file. To be used as client and server certificate.
ssl_ca	Path of file with SSL Certificate Authorities that are trusted.
ssl_capath	Path of directory containing certificates

Server Configuration Variable	Plugin Configuration Variable	Description
ssl_ca	ssl_ca	for SSL Certificate Authorities that are trusted.
ssl_crl	ssl_crl	of file containing the certificate revocation lists.
ssl_crlpath	ssl_crlpath	of directory containing revoked certificate lists.
ssl_cipher	ssl_cipher	ciphers to use while encrypting data over the connection.
tls_version	tls_version	communication will use this version and its protocols.

These options are MySQL Server configuration options which Group Replication relies on for its configuration. In addition there is the following Group Replication specific option to configure SSL on the plugin itself.

- `group_replication_ssl_mode` - specifies the security state of the connection between Group Replication members.

Table 18.4 group_replication_ssl_mode configuration values

Value	Description
DISABLED	an

Value	Description
DISABLED	unencrypted connection (*default*).
REQUIRED	establish a secure connection if the server supports secure connections.
VERIFY_CA	like REQUIRED, but additionally verify the server TLS certificate against the configured Certificate Authority (CA) certificates.
VERIFY_IDENTITY	like VERIFY_CA, but additionally verify that the server certificate matches the host to which the connection is attempted.

The following example shows an example my.cnf file section used to configure SSL on a server and how activate it for Group Replication.

```
[mysqld]
ssl_ca = "cacert.pem"
ssl_capath = "/.../ca_directory"
ssl_cert = "server-cert.pem"
ssl_cipher = "DHE-RSA-AEs256-SHA"
```

```
ssl_crl = "crl-server-revoked.crl"
ssl_crlpath = "/.../crl_directory"
ssl_key = "server-key.pem"
group_replication_ssl_mode= REQUIRED
```

The only plugin specific configuration option that is listed is `group_replication_ssl_mode`. This option activates the SSL communication between members of the group, by configuring the SSL framework with the `ssl_*` parameters that are provided to the server.

18.6 Group Replication Performance

This section explains how to use the available configuration options to gain the best performance from your replication group.

18.6.1 Fine Tuning the Group Communication Thread

The group communication thread (GCT) runs in a loop while the Group Replication plugin is loaded. The GCT receives messages from the group and from the plugin, handles quorum and failure detection related tasks, sends out some keep alive messages and also handles the incoming and outgoing transactions from/to the server/group. The GCT waits for incoming messages in a queue. When there are no messages, the GCT waits. By configuring this wait to be a little longer (doing an active wait) before actually going to sleep can prove to be beneficial in some cases. This is because the alternative is for the operating system to switch out the GCT from the processor and do a context switch.

To force the GCT to do an active wait, use the `group_replication_poll_spin_loops` option, which makes the GCT loop, doing nothing relevant for the configured number of loops, before actually polling the queue for the next message.

For example:

```
mysql> SET GLOBAL group_replication_poll_spin_loops= 10000;
```

18.6.2 Flow Control

Group Replication ensures that a transaction only commits after a majority of the members in a group have received it and agreed on the relative order between all transactions that were sent concurrently.

This approach works well if the total number of writes to the group does not exceed the write capacity of any member in the group. If it does and some of the members have less write throughput than others, particularly less than the writer members, those members can start lagging behind of the writers.

Having some members lagging behind the group brings some problematic consequences, particularly, the reads on such members may externalize very old data. Depending on why the member is lagging behind, other members in the group may have to save more or less replication context to be able to fulfil potential data transfer requests from the slow member.

There is however a mechanism in the replication protocol to avoid having too much distance, in terms of transactions applied, between fast and slow members. This is known as the flow control mechanism. It tries to address several goals:

1. to keep the members close enough to make buffering and de-synchronization between members a small problem;
2. to adapt quickly to changing conditions like different workloads or more writers in the group;
3. to give each member a fair share of the available write capacity;
4. to not reduce throughput more than strictly necessary to avoid wasting resources.

Given the design of Group Replication, the decision whether to throttle or not may be decided taking into account two work queues: *(i)* the *certification* queue; *(ii)* and on the binary log *applier*

queue. Whenever the size of one of these queues exceeds the user-defined threshold, the throttling mechanism is triggered. Only configure: *(i)* whether to do flow control at the certifier or at the applier level, or both; and *(ii)* what is the threshold for each queue.

The flow control depends on two basic mechanisms:

1. the monitoring of members to collect some statistics on throughput and queue sizes of all group members to make educated guesses on what is the maximum write pressure each member should be subjected to;
2. the throttling of members that are trying to write beyond their fair-share of the available capacity at each moment in time.

18.6.2.1 Probes and Statistics

The monitoring mechanism works by having each member deploying a set of probes to collect information about its work queues and throughput. It then propagates that information to the group periodically to share that data with the other members.

Such probes are scattered throughout the plugin stack and allow one to establish metrics, such as:

- the certifier queue size;
- the replication applier queue size;
- the total number of transactions certified;
- the total number of remote transactions applied in the member;
- the total number of local transactions.

Once a member receives a message with statistics from another member, it calculates additional metrics regarding how many transactions were certified, applied and locally executed in the last monitoring period.

Monitoring data is shared with others in the group periodically. The monitoring period must be high enough to allow the other members to decide on the current write requests, but low enough that it has minimal impact on group bandwidth. The information is shared every second, and this period is sufficient to address both concerns.

18.6.2.2 Group Replication Throttling

Based on the metrics gathered across all servers in the group, a throttling mechanism kicks in and decides whether to limit the rate a member is able to execute/commit new transactions.

Therefore, metrics acquired from all members are the basis for calculating the capacity of each member: if a member has a large queue (for certification or the applier thread), then the capacity to execute new transactions should be close to ones certified or applied in the last period.

The lowest capacity of all the members in the group determines the real capacity of the group, while the number of local transactions determines how many members are writing to it, and, consequently, how many members should that available capacity be shared with.

This means that every member has an established write quota based on the available capacity, in other words a number of transactions it can safely issue for the next period. The writer-quota will be enforced by the throttling mechanism if the queue size of the certifier or the binary log applier exceeds a user-defined threshold.

The quota is reduced by the number of transactions that were delayed in the last period, and then also further reduced by 10% to allow the queue that triggered the problem to reduce its size. In order to avoid large jumps in throughput once the queue size goes beyond the threshold, the throughput is only allowed to grow by the same 10% per period after that.

The current throttling mechanism does not penalize transactions below quota, but delays finishing those transactions that exceed it until the end of the monitoring period. As a consequence, if the quota is very small for the write requests issued some transactions may have latencies close to the monitoring period.

18.6.3 Message Compression

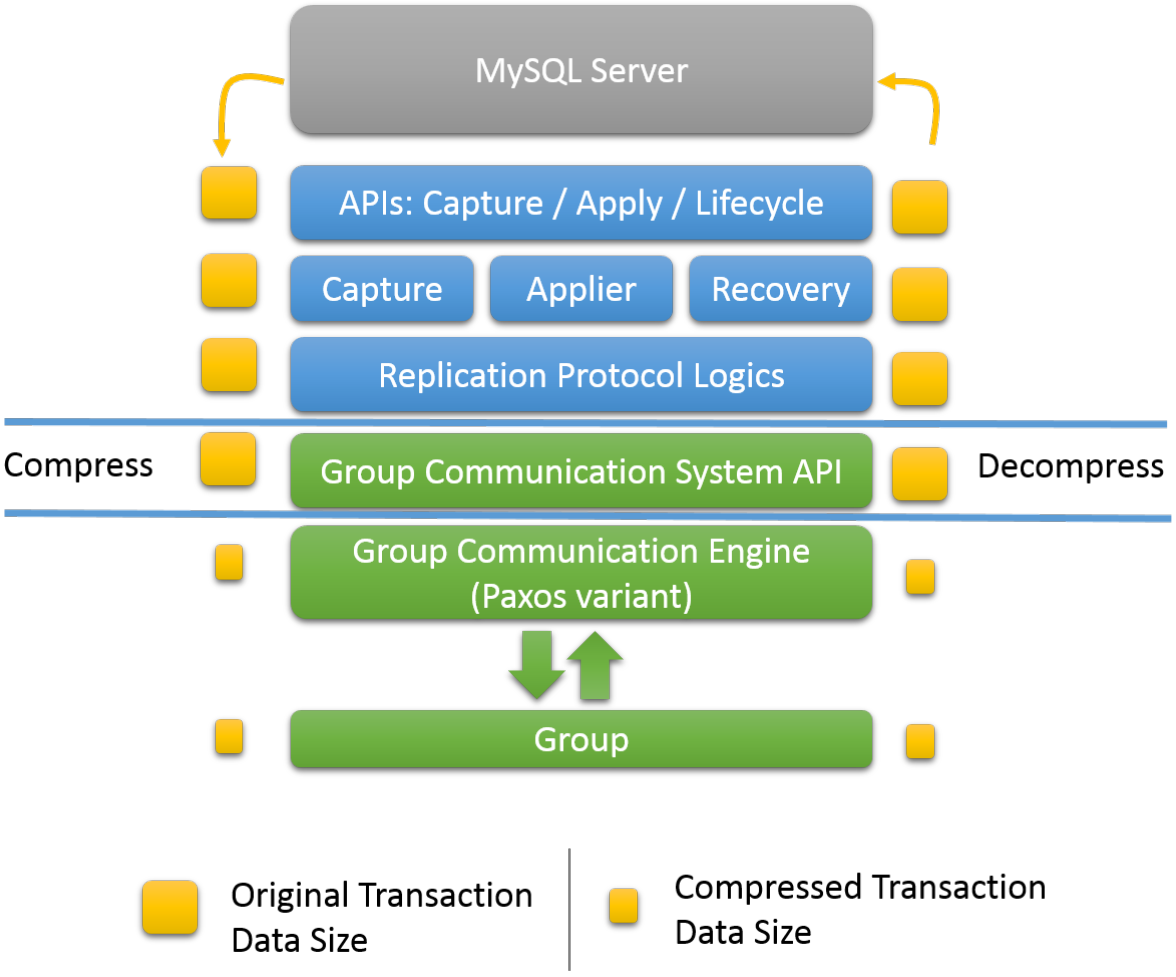
When network bandwidth is a bottleneck, message compression can provide up to 30-40% throughput improvement at the group communication level. This is especially important within the context of large groups of servers under load.

Table 18.5 LZ4 Compression Ratios for Different Binary Log Formats

Workload for STMT	Ratio
mysqlslapd	4.5
sysbench	3.4

The TCP peer-to-peer nature of the interconnections between *N* participants on the group makes the sender send the same amount of data *N* times. Furthermore, binary logs are likely to exhibit a high compression ratio (see table above). This makes compression a compelling feature for workloads that contain large transaction.

Figure 18.9 Compression Support



Compression happens at the group communication engine level, before the data is handed over to the group communication thread, so it happens within the context of the mysql user session thread. Transaction payloads may be compressed before being sent out to the group and decompressed when received. Compression is conditional and depends on a configured threshold. By default compression is enabled.

In addition, there is no requirement that all servers in the group have compression enabled to be able to work together. Upon receiving a message, the member checks the message envelope to verify whether it is compressed or not. If needed, then the member decompresses the transaction, before delivering it to the upper layer.

The compression algorithm used is LZ4. Compression is enabled by default with threshold of 1000000 bytes. The compression threshold, in bytes, may be set to something larger than default. In that case, only transactions that have a payload larger than the threshold are compressed. Below is an example of how to set a compression threshold.

```
STOP GROUP_REPLICATION;
SET GLOBAL group_replication_compression_threshold= 2097152;
START GROUP_REPLICATION;
```

This sets the compression threshold to 2MB. If a transaction generates a replication message with a payload larger than 2MB, for example a binary log transaction entry larger than 2MB, then it is compressed. To disable compression set threshold to 0.

18.6.4 Message Fragmentation

When an abnormally large message is sent between Group Replication group members, it can result in some group members being reported as failed and expelled from the group. This is because the single thread used by the group communication engine (XCom, a Paxos variant) is occupied processing the message for too long, so some of the group members might report the receiver as failed. From MySQL 8.0.16, by default, large messages are automatically split into fragments that are sent separately and reassembled by the recipients.

The system variable `group_replication_communication_max_message_size` specifies a maximum message size for Group Replication communications, above which messages are fragmented. The default maximum message size is 10485760 bytes (10 MiB). The greatest permitted value is the same as the maximum value of the `slave_max_allowed_packet` system variable, which is 1073741824 bytes (1 GB). To switch off fragmentation, specify a zero value for `group_replication_communication_max_message_size`. As with most other Group Replication system variables, you must restart the Group Replication plugin for the change to take effect. For example:

```
STOP GROUP_REPLICATION;
SET GLOBAL group_replication_communication_max_message_size= 5242880;
START GROUP_REPLICATION;
```

Message delivery for a fragmented message is considered complete when all the fragments of the message have been received and reassembled by all the group members. Fragmented messages include information in their headers that enables a member joining during message transmission to recover the earlier fragments that were sent before it joined. If the joining member fails to recover the fragments, it expels itself from the group.

In order for a replication group to use fragmentation, all group members must be at MySQL 8.0.16 or above, and the Group Replication communication protocol version in use by the group must allow fragmentation. You can inspect the communication protocol in use by a group by using the `group_replication_get_communication_protocol()` UDF, which returns the oldest MySQL Server version that the group supports. Versions from MySQL 5.7.14 allow compression of messages, and versions from MySQL 8.0.16 also allow fragmentation of messages. If all group members are

at MySQL 8.0.16 or above and there is no requirement to allow members at earlier releases to join, you can use the `group_replication_set_communication_protocol()` UDF to set the communication protocol version to MySQL 8.0.16 or above in order to allow fragmentation. For more information, see Section 18.4.2.4, “Setting a Group's Communication Protocol Version”.

If a replication group cannot use fragmentation because some members do not support it, the system variable `group_replication_transaction_size_limit` can be used to limit the maximum size of transactions the group accepts. In MySQL 8.0, the default setting is approximately 143 MB. Transactions above this size are rolled back. You can also use the system variable `group_replication_member_expel_timeout` to allow additional time (up to an hour) before a member under suspicion of having failed is expelled from the group.

18.6.5 XCom Cache Management

The group communication engine for Group Replication (XCom, a Paxos variant) includes a cache for messages (and their metadata) exchanged between the group members as a part of the consensus protocol. Among other functions, the message cache is used for recovery by members that return to the group after a period where they were unable to communicate with the other group members.

From MySQL 8.0.16, a cache size limit can be set for XCom's message cache using the `group_replication_message_cache_size` system variable. This system variable has a default and minimum setting of 1 GB, which is the size of the message cache in MySQL Server versions prior to MySQL 8.0.16. If the cache size limit is reached, XCom removes the oldest entries that have been decided and delivered. Ensure that sufficient memory is available on your system for your chosen cache size limit, considering the size of MySQL Server's other caches and object pools.

If a rejoining member requires a message for recovery, but the message has already been removed from the message cache, the member cannot rejoin. This situation is more likely to occur if you have used the `group_replication_member_expel_timeout` system variable (introduced in MySQL 8.0.13) to specify an additional delay time before suspect members are expelled from a group. The Group Communication System (GCS) alerts you, by a warning message, when a message that is likely to be needed for recovery by a member that is currently unreachable is removed from the message cache. This warning message is logged on all the active group members (only once for each unreachable member). Although the group members cannot know for sure what message was the last message seen by the unreachable member, the warning message indicates that the cache size might not be sufficient to support your chosen waiting period before a member is expelled. In this situation, consider increasing the cache size limit with reference to the expected volume of messages in the time period specified by the `group_replication_member_expel_timeout` system variable, so that the cache contains all the missed messages required for members to return successfully. You can also consider increasing the cache size limit temporarily if you expect a member to become unreachable for an unusual period of time.

If you are considering reducing the cache size limit, you can query the Performance Schema table `memory_summary_global_by_event_name` using the following statement:

```
SELECT * FROM performance_schema.memory_summary_global_by_event_name
  WHERE EVENT_NAME LIKE 'memory/group_rpl/GCS_XCom::xcom_cache';
```

This returns memory usage statistics for the message cache, including the current number of cached entries and current size of the cache. If you reduce the cache size limit, XCom removes the oldest entries that have been decided and delivered until the current size is below the limit. XCom might temporarily exceed the cache size limit while this removal process is ongoing.

18.6.6 Responses to Failure Detection and Network Partitioning

Group Replication's failure detection mechanism is designed to identify group members that are no longer communicating with the group, and expel them as and when it seems likely that they have

failed. Having a failure detection mechanism increases the chance that the group contains a majority of correctly working members, and that requests from clients are therefore processed correctly.

Normally, all group members regularly exchange messages with all other group members. If a group member does not receive any messages from a particular fellow member for 5 seconds, when this detection period ends, it creates a suspicion of the fellow member. When a suspicion times out, the suspected member is assumed to have failed, and is expelled from the group. An expelled member is removed from the membership list seen by the other members, but it does not know that it has been expelled from the group, so it sees itself as online and the other members as unreachable. If the member has not in fact failed (for example, because it was just disconnected due to a temporary network issue) and it is able to resume communication with the other members, it receives a view containing the information that it has been expelled from the group.

The responses of group members, including the failed member itself, to these situations can be configured at a number of points in the process. By default, the following behaviors happen if a member is suspected of having failed:

1. When a suspicion is created, it times out immediately (its lifetime is set to 0), so the suspected member is expelled as soon as the expired suspicion is identified. The member could potentially survive for a further few seconds after the timeout because the check for expired suspicions is carried out periodically.

2. If an expelled member resumes communication and realises that it was expelled, it does not try to rejoin the group and accepts its expulsion.

3. When an expelled member accepts its expulsion, it switches to super read only mode and awaits operator attention. (The exception is in releases from MySQL 8.0.12 to 8.0.15, where the default was for the member to shut itself down. From MySQL 8.0.16, the behavior was changed to match the behavior in MySQL 5.7.)

These defaults are set to prioritize the correct operation of the group and the correct handling of requests. However, they might be inconvenient in the case of slower networks or networks with a high rate of transient failures, because in these situations there could be a frequent requirement for operator intervention to fix expelled members. They also do not allow for continued operation of the group to be planned in the case of expected network failures or machine slowdowns. You can use Group Replication configuration options to change these behaviors either permanently or temporarily, to suit your system's requirements and your priorities, as follows:

1. You can use the `group_replication_member_expel_timeout` system variable, which is available from MySQL 8.0.13, to allow additional time between the creation of a suspicion and the expulsion of the suspect member. You can set the lifetime of the suspicion up to 3600 seconds (one hour) before it times out. (The 5-second detection period before a suspicion is created is not configurable.) Suspect members in this state are listed as `UNREACHABLE`, but are not removed from the group's membership list.

   Bear in mind that while a group has unreachable members, you cannot add or remove any other members or elect a new primary. If you do want to take one of these actions and you cannot make the suspect member active again, you can force the suspicion to time out by changing `group_replication_member_expel_timeout` on any online member to a value less than the time that has already elapsed since the suspicion was created.

2. You can use the `group_replication_autorejoin_tries` system variable, which is available from MySQL 8.0.16, to make an expelled member that is able to resume communication automatically try to rejoin the group. You can specify a number of attempts that the member makes to rejoin the group, instead of just accepting its expulsion as soon as it resumes communication. When the member's expulsion or unreachable majority timeout is reached, it makes an attempt to rejoin (using the same settings as it used previously), then continues to make further auto-rejoin attempts up to the specified number of tries. After an unsuccessful auto-rejoin attempt, the member waits 5 minutes before the next try. During the auto-rejoin procedure, the expelled member remains in super read only mode and displays an `ERROR` state to the replication group.

Bear in mind that while a member remains in this mode, although writes cannot be made on the member, reads can, with an increasing likelihood of stale reads over time. If you do want to intervene to take the member offline, the member can be stopped manually at any time by using a `STOP GROUP_REPLICATION` statement or shutting down the server. You can monitor the auto-rejoin procedure using the Performance Schema. While an auto-rejoin procedure is taking place, the Performance Schema table `events_stages_current` shows the event “Undergoing auto-rejoin procedure”, with the number of retries that have been attempted so far during this instance of the procedure (in the `WORK_COMPLETED` field). The `events_stages_summary_global_by_event_name` table shows the number of times the server instance has initiated the auto-rejoin procedure (in the `COUNT_STAR` field). The `events_stages_history_long` table shows the time each of these auto-rejoin procedures was completed (in the `TIMER_END` field).

3. You can use the `group_replication_exit_state_action` system variable, which is available from MySQL 8.0.12 and MySQL 5.7.24, to choose whether an expelled member that fails to rejoin (or does not try) shuts down MySQL Server or switches itself to super read only mode. As with the auto-rejoin process, if the member goes to super read only mode, there is a probability of stale reads which increases over time. Instructing the member to shut itself down ends this situation and means that you do not need to pro-actively monitor the servers for failures, but it means that the MySQL Server instance is unavailable and must be restarted. Operator intervention is required whatever exit action is set, as an ex-member that has exhausted its auto-rejoin attempts (or never had any) and has been expelled from the group is not allowed to rejoin without a restart of Group Replication.

Important

The exit action specified by `group_replication_exit_state_action` is not taken if a failure occurs during the local configuration check, or if there is a mismatch between the configuration of the joining member and the configuration of the group. In these situations, the `super_read_only` system variable is left with its original value, and the server does not shut down MySQL. To ensure that the server cannot accept updates when Group Replication did not start, we therefore recommend that `super_read_only=ON` is set in the server's configuration file at startup, and then changed to `OFF` after Group Replication has been started successfully.

Note that where group members are at an older MySQL Server release that does not support a relevant setting, or at a release with a different default, they act towards themselves and other group members according to the default behaviors stated above. For example, a member that does not support the `group_replication_member_expel_timeout` system variable expels other members as soon as an expired suspicion is detected, and this expulsion is accepted by other members even if they support the system variable and have a longer timeout set.

Network Partitioning

Members that have not failed might lose contact with part, but not all, of the replication group due to a network partition. For example, in a group of 5 servers (S1,S2,S3,S4,S5), if there is a disconnection between (S1,S2) and (S3,S4,S5) there is a network partition. The first group (S1,S2) is now in a minority because it cannot contact more than half of the group. Any transactions that are processed by the members in the minority group are blocked, because the majority of the group is unreachable, therefore the group cannot achieve quorum. If the servers in the majority group are still online, they can automatically form their own functional partition and continue to function as a replication group. For a detailed description of this scenario, see Section 18.4.5, “Network Partitioning”.

In this situation, the default behavior is for the members in both the minority and the majority to remain in the group, continue to accept transactions (although they are blocked on the members in the minority), and wait for operator intervention. The intervention process, which is described in

Section 18.4.5, “Network Partitioning”, involves checking which servers are functioning and forcing a new group membership if necessary.

If you do not want to pro-actively monitor for this situation, and want to avoid the possibility of creating a split-brain situation (with two versions of the group membership) due to inappropriate intervention, you can instruct members that find themselves in a minority to exit the group after a timeout period. The system variable `group_replication_unreachable_majority_timeout` sets a number of seconds for a member to wait after losing contact with the majority of group members. After this time, all pending transactions that have been processed by the member and the others in the minority group are rolled back, and the servers in that group move to the `ERROR` state, then follow the exit action specified by `group_replication_exit_state_action`.

18.7 Upgrading Group Replication

This section explains how to upgrade a group replication setup. The basic process of upgrading members of a group is the same as upgrading stand-alone instances, see Section 2.11, “Upgrading MySQL” for the actual process of doing upgrade and types available. Choosing between an in-place or logical upgrade depends on the amount of data stored in the group. Usually an in-place upgrade is faster, and therefore is recommended. Due to the distributed nature of Group Replication, there are considerations such as what order to upgrade members of a group, which are described in this section. You should also consult Section 17.4.3, “Upgrading a Replication Setup”.

If your group can be taken fully offline see Section 18.7.1, “Group Replication Offline Upgrade”. If your group needs to remain online, as is common with production deployments, see Section 18.7.2, “Group Replication Online Upgrade” for the different approaches available for upgrading a group with minimal downtime.

18.7.1 Group Replication Offline Upgrade

To perform an offline upgrade of a Group Replication group, you remove each member from the group, perform an upgrade of the member and then restart the group as usual. In a multi-primary group you can shutdown the members in any order. In a single-primary group, shutdown each secondary first and then finally the primary. See Section 18.7.2.3, “Upgrading a Group Replication Member” for how to remove members from a group and shutdown MySQL.

Once the group is offline, upgrade all of the members. See Section 2.11, “Upgrading MySQL” for how to perform an upgrade. When all members have been upgraded, restart the members.

If you upgrade all the members of a replication group when they are offline and then restart the group, the members join using the new release's Group Replication communication protocol version, so that becomes the group's communication protocol version. If you have a requirement to allow members at earlier releases to join, you can use the `group_replication_set_communication_protocol()` UDF to downgrade the communication protocol version, specifying the MySQL Server version of the prospective group member that has the oldest installed server version.

18.7.2 Group Replication Online Upgrade

When you have a group running which you want to upgrade but you need to keep the group online to serve your application, you need to consider your approach to the upgrade. This section describes the different elements involved in an online upgrade, and various methods of how to upgrade your group.

18.7.2.1 Online Upgrade Considerations

When upgrading an online group you should consider the following points:

- Regardless of the way which you upgrade your group, it is important to disable any writes to group members until they are ready to rejoin the group.

- When a member is stopped, the `super_read_only` variable is set to on automatically, but this change is not persisted.
- When MySQL 5.7.22 or MySQL 8.0.11 tries to join a group running MySQL 5.7.21 or lower it fails to join the group because MySQL 5.7.21 does not send its value of `lower_case_table_names`.

18.7.2.2 Combining Group Replication Versions

When you upgrade an online group, you might need to run different versions of MySQL on members in the group at the same time. Depending on the changes made between the versions of MySQL, you could encounter incompatibilities. For example, if a feature has been deprecated between major versions then combining the versions in a group might cause members which rely on the deprecated feature to fail. This section describes the best practices for combining members running different versions of MySQL in the same group.

Group Replication is versioned according to the server version which the plugin was bundled with, for example if a member is running MySQL 5.7.19 then that is the version of the plugin. This version number is critical when upgrading a group, and specifically at the time of joining members to a group. See Section 2.1.1, “Which MySQL Version and Distribution to Install”.

To check the version of MySQL on a group member issue:

```
SELECT MEMBER_HOST,MEMBER_PORT,MEMBER_VERSION FROM performance_schema.replication_group_members;
+-------------+-------------+----------------+
| member_host | member_port | member_version |
+-------------+-------------+----------------+
| example.com |    3306     |   8.0.13       |
+-------------+-------------+----------------+
```

The rules for combining members in a group with different major versions are:

- You cannot join a member to a group when it is running an older major version than the major version which the existing group members are running. For example if you have a group with members running MySQL version 8.0, you cannot add a member which is running an older version such as MySQL version 5.7.
- You can join a member to group if it is running a newer major version than the major version which the existing group members are running. For example if you have a group with members running MySQL 5.7, you can add a member running MySQL version 8.0, but it remains in read-only mode. Writing to this member while there are read-write members running an older MySQL version is dangerous and must be avoided.

The rules for combining members in a group with different minor versions are:

- You can add members running a newer or older minor version to a group, they are able to do writes. In a single-primary group, added members default to being read-only.

A replication group uses a Group Replication communication protocol version that can differ from the MySQL Server version of the members. To check the group's communication protocol version, issue the following statement on any member:

```
SELECT group_replication_get_communication_protocol();
```

The return value shows the oldest MySQL Server version that can join this group and use the group's communication protocol. Versions from MySQL 5.7.14 allow compression of messages, and versions from MySQL 8.0.16 also allow fragmentation of messages. Note that the `group_replication_get_communication_protocol()` UDF returns the minimum MySQL version that the group supports, which might differ from the version number that was passed to the

`group_replication_set_communication_protocol()` UDF, and from the MySQL Server version that is installed on the member where you use the UDF.

When you upgrade all the members of a replication group to a new MySQL Server release, the Group Replication communication protocol version is not automatically upgraded, in case there is still a requirement to allow members at earlier releases to join. If you do not need to support older members and want to allow the upgraded members to use any added communication capabilities, after the upgrade use the `group_replication_set_communication_protocol()` UDF to upgrade the communication protocol, specifying the new MySQL Server version to which you have upgraded the members. For more information, see Section 18.4.2.4, "Setting a Group's Communication Protocol Version".

18.7.2.3 Upgrading a Group Replication Member

This section explains the steps required for upgrading a member of a group. This procedure is part of the methods described at Section 18.7.2.4, "Group Replication Online Upgrade Methods". The process of upgrading a member of a group is common to all methods and is explained first. The way which you join upgraded members can depend on which method you are following, and other factors such as whether the group is operating in single-primary or multi-primary mode. How you upgrade the server instance, using either the in-place or provision approach, does not impact on the methods described here.

The process of upgrading a member consists of removing it from the group, following your chosen method of upgrading the member, and then rejoining the upgraded member to a group. The recommended order of upgrading members in a single-primary group is to upgrade all secondaries, and then upgrade the primary last. If the primary is upgraded before a secondary, a new primary using the older MySQL version is chosen, but there is no need for this step.

To upgrade a member of a group:

- Connect a client to the group member and issue `STOP GROUP_REPLICATION`. Before proceeding, ensure that the member's status is `OFFLINE` by monitoring the `replication_group_members` table.
- Disable Group Replication from starting up automatically so that you can safely connect to the member after upgrading and configure it without it rejoining the group by setting `group_replication_start_on_boot=0`.

Important

If an upgraded member has `group_replication_start_on_boot=1` then it could rejoin the group before you can perform the MySQL upgrade procedure and could result in issues. For example, if the upgrade fails and the server restarts again, then a possibly broken server could try to join the group.

- Stop the member, for example using `mysqladmin shutdown` or the `SHUTDOWN` statement. Any other members in the group continue running.
- Upgrade the member, using the in-place or provisioning approach. See Section 2.11, "Upgrading MySQL" for details. When restarting the upgraded member, because `group_replication_start_on_boot` is set to 0, Group Replication does not start on the instance, and therefore it does not rejoin the group.
- Once the MySQL upgrade procedure has been performed on the member, `group_replication_start_on_boot` must be set to 1 to ensure Group Replication starts correctly after restart. Restart the member.
- Connect to the upgraded member and issue `START GROUP_REPLICATION`. This rejoins the member to the group. The Group Replication metadata is in place on the upgraded server, therefore there is usually no need to reconfigure Group Replication. The server has to catch up with any

transactions processed by the group while the server was offline. Once it has caught up with the group, it becomes an online member of the group.

Note

the longer it takes to upgrade a server, the more time that member is offline and therefore the more time it takes for the server to catch up when added back to the group.

When an upgraded member joins a group which has any member running an earlier version, the upgraded member joins with `super_read_only=on`, regardless of whether it was a primary or secondary. This ensures that no writes are made to upgraded members until all members are running the newer version. In a multi-primary group, once you are sure the upgrade has been successful and the group is ready to process transactions, it is necessary to manually configure members which should become writeable primaries. Connect to each member and issue:

```
SET GLOBAL read_only=off;
```

18.7.2.4 Group Replication Online Upgrade Methods

Choose one of the following methods of upgrading a Group Replication group:

Rolling In-Group Upgrade

This method is supported provided that servers running a newer major version are not generating workload to the group while there are still servers with an older version in it. In other words servers with a newer major version can join the group only as secondaries. In this method there is only ever one group, and each server instance is removed from the group, upgraded and then rejoined to the group. Members running the newer version join the group with `super_read_only=ON`. This method is well suited to single-primary groups. When the group is operating in single-primary mode, the primary member should be the last member to be upgraded. If the primary is upgraded while there are still members running the old version, a new primary is chosen from the members running the old version, but there is no need for this.

For groups operating in single-primary mode, once all secondaries are running the newer version, when the primary member leaves the group to be upgraded, a new primary is automatically chosen from the members running the new version. For groups operating in multi-primary mode, once *all* members are upgraded, you *must* manually set `super_read_only=OFF` on each member that should function as a primary. For groups operating in multi-primary mode, during this process the number of primaries is decreased, causing a reduction in write availability. This does not impact groups operating in single-primary mode.

Rolling Migration Upgrade

In this method you remove members from the group, upgrade them and then create a second group using the upgraded members. For groups operating in multi-primary mode, during this process the number of primaries is decreased, causing a reduction in write availability. This does not impact groups operating in single-primary mode.

Because the group running the older version is online while you are upgrading the members, you need the group running the newer version to catch up with any transactions executed while the members were being upgraded. Therefore one of the servers in the new group is configured as a replication slave of a primary from the older group. This ensures that the new group catches up with the older group. Because this method relies on an asynchronous replication channel which is used to replicate data from one group to another, it is supported under the same assumptions and requirements of master-slave replication, see Chapter 17, *Replication*. For groups operating in single-primary mode, the asynchronous replication connection to the old group must send data to the primary in the new group, for a multi-primary group the asynchronous replication channel can connect to any primary.

The process is to:

- remove members from the original group running the older server version one by one, see Section 18.7.2.3, “Upgrading a Group Replication Member”
- upgrade the server version running on the member, see Section 2.11, “Upgrading MySQL”. You can either follow an in-place or provision approach to upgrading.
- create a new group with the upgraded members, see Chapter 18, *Group Replication*. In this case you need to configure a new group name on each member (because the old group is still running and using the old name), bootstrap an initial upgraded member, and then add the remaining upgraded members.
- set up an asynchronous replication channel between the old group and the new group, see Section 17.1.3.4, “Setting Up Replication Using GTIDs”. Configure the older primary to function as the asynchronous replication master and the new group member as a GTID-based replication slave.

Before you can redirect your application to the new group, you must ensure that the new group has a suitable number of members, for example so that the group can handle the failure of a member. Issue `SELECT * FROM performance_schema.replication_group_members` and compare the initial group size and the new group size. Wait until all data from the old group is propagated to the new group and then drop the asynchronous replication connection and upgrade any missing members.

Rolling Duplication Upgrade

In this method you create a second group consisting of members which are running the newer version, and the data missing from the older group is replicated to the newer group. This assumes that you have enough servers to run both groups simultaneously. Due to the fact that during this process the number of primaries is *not* decreased, for groups operating in multi-primary mode there is no reduction in write availability. This makes rolling duplication upgrade well suited to groups operating in multi-primary mode. This does not impact groups operating in single-primary mode.

Because the group running the older version is online while you are provisioning the members in the new group, you need the group running the newer version to catch up with any transactions executed while the members were being provisioned. Therefore one of the servers in the new group is configured as a replication slave of a primary from the older group. This ensures that the new group catches up with the older group. Because this method relies on an asynchronous replication channel which is used to replicate data from one group to another, it is supported under the same assumptions and requirements of master-slave replication, see Chapter 17, *Replication*. For groups operating in single-primary mode, the asynchronous replication connection to the old group must send data to the primary in the new group, for a multi-primary group the asynchronous replication channel can connect to any primary.

The process is to:

- deploy a suitable number of members so that the group running the newer version can handle failure of a member
- take a backup of the existing data from a member of the group
- use the backup from the older member to provision the members of the new group, see Section 18.7.2.5, “Group Replication Upgrade with `mysqlbackup`” for one method.

Note

You must restore the backup to the same version of MySQL which the backup was taken from, and then perform an in-place upgrade. For instructions, see Section 2.11, “Upgrading MySQL”.

- create a new group with the upgraded members, see Chapter 18, *Group Replication*. In this case you need to configure a new group name on each member (because the old group is still running and

using the old name), bootstrap an initial upgraded member, and then add the remaining upgraded members.

- set up an asynchronous replication channel between the old group and the new group, see Section 17.1.3.4, “Setting Up Replication Using GTIDs”. Configure the older primary to function as the asynchronous replication master and the new group member as a GTID-based replication slave.

Once the ongoing data missing from the newer group is small enough to be quickly transferred, you must redirect write operations to the new group. Wait until all data from the old group is propagated to the new group and then drop the asynchronous replication connection.

18.7.2.5 Group Replication Upgrade with `mysqlbackup`

As part of a provisioning approach you can use MySQL Enterprise Backup to copy and restore the data from a group member to new members. However you cannot use this technique to directly restore a backup taken from a member running an older version of MySQL to a member running a newer version of MySQL. The solution is to restore the backup to a new server instance which is running the same version of MySQL as the member which the backup was taken from, and then upgrade the instance. This process consists of:

- Take a backup from a member of the older group using `mysqlbackup`. See Section 18.4.7, “Using MySQL Enterprise Backup with Group Replication”.
- Deploy a new server instance, which must be running the same version of MySQL as the older member where the backup was taken.
- Restore the backup from the older member to the new instance using `mysqlbackup`.
- Upgrade MySQL on the new instance, see Section 2.11, “Upgrading MySQL”.

Repeat this process to create a suitable number of new instances, for example to be able to handle a failover. Then join the instances to a group based on the Section 18.7.2.4, “Group Replication Online Upgrade Methods”.`

18.8 Group Replication System Variables

These are the system variables that are specific to the Group Replication plugin. Every configuration option is prefixed with "group_replication".

Important

- Although most variables are described as dynamic and can be changed while the server is running, most changes only take effect upon restarting the Group Replication plugin. Variables which can be changed without requiring a restart of the plugin are specifically noted as such in this section.
- Variables that specify IP addresses or host names for group members are not validated until a `START GROUP_REPLICATION` statement is issued. The Group Communication System (GCS) is not available to validate the values until that point.
- A number of variables for Group Replication are not completely validated during server startup if they are passed as command line arguments to the server. These variables include `group_replication_group_name`, `group_replication_single_primary_mode`, `group_replication_force_members`, the SSL variables, and the flow control variables. They are only fully validated after the server has started.

- `group_replication_allow_local_disjoint_gtids_join`

Property	Value
Command-Line Format	`--group-replication-allow-local-disjoint-gtids-join=value`
Deprecated	Yes (removed in 8.0.4)
System Variable	`group_replication_allow_local_disjoint_gtid`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	`OFF`

Removed in version 8.0.4. Allow the current server to join the group even if it has transactions not present in the group.

Warning

Use caution when enabling this option as incorrect usage could lead to inconsistencies in the group.

- `group_replication_allow_local_lower_version_join`

Property	Value
Command-Line Format	`--group-replication-allow-local-lower-version-join=value`
System Variable	`group_replication_allow_local_lower_version`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	`OFF`

Allow the current server to join the group even if it has a lower plugin version than the group.

- `group_replication_auto_increment_increment`

Property	Value
Command-Line Format	`--group-replication-auto-increment-increment=value`
System Variable	`group_replication_auto_increment_increment`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`7`
Minimum Value	`1`
Maximum Value	`65535`

Determines the interval between successive column values for transactions that execute on this server instance.

- `group_replication_autorejoin_tries`

Property	Value
Command-Line Format	`--group-replication-autorejoin-tries=value`
Introduced	8.0.16
System Variable	`group_replication_autorejoin_tries`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`0`
Minimum Value	`0`
Maximum Value	`2016`

Specifies the number of tries that a member makes to automatically rejoin the group if it is expelled, or if it is unable to contact a majority of the group before the `group_replication_unreachable_majority_timeout` setting is reached. The default setting, 0, means that the member does not try to rejoin, and proceeds to the action specified by the `group_replication_exit_state_action` system variable. You can specify a maximum of 2016 tries.

Activate auto-rejoin if you can tolerate the possibility of stale reads and want to minimize the need for manual intervention, especially where transient network issues fairly often result in the expulsion of members. If you specify a number of tries, when the member's expulsion or unreachable majority timeout is reached, it makes an attempt to rejoin (using the same settings as it used previously), then continues to make further auto-rejoin attempts up to the specified number of tries. After an unsuccessful auto-rejoin attempt, the member waits 5 minutes before the next try. During the auto-rejoin procedure, the member remains in super read only mode and displays an `ERROR` state to the replication group. The member can be stopped manually at any time by using a `STOP GROUP_REPLICATION` statement or shutting down the server. If the specified number of tries is exhausted without the member rejoining or being stopped, the member proceeds to the action specified by the `group_replication_exit_state_action` system variable, which can be either remaining in super read only mode or shutting down.

For more information on configuring member behavior in failure detection situations, see Section 18.6.6, “Responses to Failure Detection and Network Partitioning”.

- `group_replication_bootstrap_group`

Property	Value
Command-Line Format	`--group-replication-bootstrap-group=value`
System Variable	`group_replication_bootstrap_group`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	`OFF`

Configure this server to bootstrap the group. This option must only be set on one server and only when starting the group for the first time or restarting the entire group. After the group has been

bootstrapped, set this option to `OFF`. It should be set to `OFF` both dynamically and in the configuration files. Starting two servers or restarting one server with this option set while the group is running may lead to an artificial split brain situation, where two independent groups with the same name are bootstrapped.

- `group_replication_communication_debug_options`

Property	Value
Command-Line Format	`--group-replication-communication-debug-options=value`
Introduced	8.0.3
System Variable	`group_replication_communication_debug_optio`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	`GCS_DEBUG_NONE`

Valid Values	`GCS_DEBUG_NONE`
	`GCS_DEBUG_BASIC`
	`GCS_DEBUG_TRACE`
	`XCOM_DEBUG_BASIC`
	`XCOM_DEBUG_TRACE`
	`GCS_DEBUG_ALL`

Configures the level of debugging messages to provide for the different Group Replication components, such as Group Communication System (GCS) and the group communication engine (XCom, a Paxos variant). The debug information is stored in the `GCS_DEBUG_TRACE` file in the data directory.

The set of available options, specified as strings, can be combined. The following options are available:

- `GCS_DEBUG_NONE` disables all debugging levels for both GCS and XCOM
- `GCS_DEBUG_BASIC` enables basic debugging information in GCS
- `GCS_DEBUG_TRACE` enables trace information in GCS
- `XCOM_DEBUG_BASIC` enables basic debugging information in XCOM
- `XCOM_DEBUG_TRACE` enables trace information in XCOM
- `GCS_DEBUG_ALL` enables all debugging levels for both GCS and XCOM

Setting the debug level to `GCS_DEBUG_NONE` only has an effect when provided without any other option. Setting the debug level to `GCS_DEBUG_ALL` overrides all other options.

- `group_replication_communication_max_message_size`

Property	Value
Command-Line Format	`--group-replication-communication-max-message-size=value`
Introduced	8.0.16
System Variable	`group_replication_communication_max_message_si`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`10485760`
Minimum Value	`0`
Maximum Value	`1073741824`

Specifies a maximum message size for Group Replication communications. Messages greater than this size are automatically split into fragments that are sent separately and reassembled by the recipients. For more information, see Section 18.6.4, “Message Fragmentation”.

A maximum message size of 10485760 bytes (10 MiB) is set by default, which means that fragmentation is used by default in releases from MySQL 8.0.16. The greatest permitted value is the same as the maximum value of the `slave_max_allowed_packet` system variable, which is 1073741824 bytes (1 GB). To switch off fragmentation, specify a zero value for `group_replication_communication_max_message_size`.

In order for members of a replication group to use fragmentation, the group's communication protocol version must be MySQL 8.0.16 or above. Use the `group_replication_get_communication_protocol()` UDF to view the group's communication protocol version. If a lower version is in use, group members do not fragment messages. You can use the `group_replication_set_communication_protocol()` UDF to set the group's communication protocol to a higher version if all group members support it. For more information, see Section 18.4.2.4, “Setting a Group's Communication Protocol Version”.

- `group_replication_components_stop_timeout`

Property	Value
Command-Line Format	`--group-replication-components-stop-timeout=value`
System Variable	`group_replication_components_stop_timeout`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`31536000`
Minimum Value	`2`
Maximum Value	`31536000`

Timeout, in seconds, that Group Replication waits for each of the components when shutting down.

- `group_replication_compression_threshold`

Property	Value
Command-Line Format	`--group-replication-compression-threshold=value`
System Variable	`group_replication_compression_threshold`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`1000000`
Minimum Value	`0`
Maximum Value	`4294967295`

The value in bytes above which (LZ4) compression is enforced. When set to zero, deactivates compression.

- `group_replication_consistency`

Property	Value
Command-Line Format	`--group-replication-consistency=value`
Introduced	8.0.14
System Variable	`group_replication_consistency`
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	`EVENTUAL`

Valid Values	`EVENTUAL`
	`BEFORE_ON_PRIMARY_FAILOVER`
	`BEFORE`
	`AFTER`
	`BEFORE_AND_AFTER`

Controls the transaction consistency guarantee which a group provides. You can configure the consistency globally or per transaction. Also configures the fencing mechanism used by newly elected primaries in single primary groups. The effect of the variable must be considered for both read only (RO) and read write (RW) transactions. The following list shows the possible values of this variable, in order of increasing transaction consistency guarantee:

- `EVENTUAL`

  Both RO and RW transactions do not wait for preceding transactions to be applied before executing. This was the behavior of Group Replication before this variable was added. A RW transaction does not wait for other members to apply a transaction. This means that a transaction could be externalized on one member before the others. This also means that in the event of a primary failover, the new primary can accept new RO and RW transactions before the

previous primary transactions are all applied. RO transactions could result in outdated values, RW transactions could result in a rollback due to conflicts.

- `BEFORE_ON_PRIMARY_FAILOVER`

  New RO or RW transactions with a newly elected primary that is applying backlog from the old primary are held (not applied) until any backlog has been applied. This ensures that when a primary failover happens, intentionally or not, clients always see the latest value on the primary. This guarantees consistency, but means that clients must be able to handle the delay in the event that a backlog is being applied. Usually this delay should be minimal, but does depend on the size of the backlog.

- `BEFORE`

  A RW transaction waits for all preceding transactions to complete before being applied. A RO transaction waits for all preceding transactions to complete before being executed. This ensures that this transaction reads the latest value by only affecting the latency of the transaction. This reduces the overhead of synchronization on every RW transaction, by ensuring synchronization is used only on RO transactions. This consistency level also includes the consistency guarantees provided by `BEFORE_ON_PRIMARY_FAILOVER`.

- `AFTER`

  A RW transaction waits until its changes have been applied to all of the other members. This value has no effect on RO transactions. This mode ensures that when a transaction is committed on the local member, any subsequent transaction reads the written value or a more recent value on any group member. Use this mode with a group that is used for predominantly RO operations to ensure that applied RW transactions are applied everywhere once they commit. This could be used by your application to ensure that subsequent reads fetch the latest data which includes the latest writes. This reduces the overhead of synchronization on every RO transaction, by ensuring synchronization is used only on RW transactions. This consistency level also includes the consistency guarantees provided by `BEFORE_ON_PRIMARY_FAILOVER`.

- `BEFORE_AND_AFTER`

  A RW transaction waits for 1) all preceding transactions to complete before being applied and 2) until its changes have been applied on other members. A RO transaction waits for all preceding transactions to complete before execution takes place. This consistency level also includes the consistency guarantees provided by `BEFORE_ON_PRIMARY_FAILOVER`.

For more information, see Section 18.4.3, “Transaction Consistency Guarantees”.

- `group_replication_enforce_update_everywhere_checks`

Property	Value
Command-Line Format	`--group-replication-enforce-update-everywhere-checks=value`
System Variable	`group_replication_enforce_update_everywhere_ch`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	`OFF`

Enable or disable strict consistency checks for multi-primary update everywhere.

- `group_replication_exit_state_action`

Property	Value
Command-Line Format	`--group-replication-exit-state-action=value`
Introduced	8.0.12
System Variable	`group_replication_exit_state_action`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value (>= 8.0.12, <= 8.0.15)	`ABORT_SERVER`
Default Value	`READ_ONLY`
Valid Values	`ABORT_SERVER` `READ_ONLY`

Configures how Group Replication behaves when a server instance leaves the group unintentionally, for example after encountering an applier error, or in the case of a loss of majority, or when another member of the group expels it due to a suspicion timing out. The timeout period for a member to leave the group in the case of a loss of majority is set by the `group_replication_unreachable_majority_timeout` system variable, and the timeout period for suspicions is set by the `group_replication_member_expel_timeout` system variable. Note that an expelled group member does not know that it was expelled until it reconnects to the group, so the specified action is only taken if the member manages to reconnect, or if the member raises a suspicion on itself and expels itself.

When a member is expelled due to a suspicion timing out or a loss of majority, if the member has the `group_replication_autorejoin_tries` system variable set to specify a number of auto-rejoin attempts, it first makes the specified number of attempts while in super read only mode, and then follows the action specified by `group_replication_exit_state_action`. Auto-rejoin attempts are not made in case of an applier error, because these are not recoverable. For more information on configuring member behavior in failure detection situations, see Section 18.6.6, “Responses to Failure Detection and Network Partitioning”.

When `group_replication_exit_state_action` is set to `ABORT_SERVER`, if the member exits the group unintentionally or exhausts its auto-rejoin attempts, the instance shuts down MySQL. This setting was the default from MySQL 8.0.12, when the system variable was added, to MySQL 8.0.15 inclusive.

When `group_replication_exit_state_action` is set to `READ_ONLY`, if the member exits the group unintentionally or exhausts its auto-rejoin attempts, the instance switches MySQL to super read only mode (by setting the system variable `super_read_only` to `ON`). This setting was the behavior for MySQL 8.0 releases before the system variable was introduced, and became the default again from MySQL 8.0.16. It is also the default from MySQL 5.7.24, when the system variable was added to that release, and the behavior for earlier MySQL 5.7 releases.

Important

The specified exit action is not taken if a failure occurs during the local configuration check, or if there is a mismatch between the configuration of the joining member and the configuration of the group. In these situations, the `START GROUP_REPLICATION` command fails, the `super_read_only` system variable is left with its original value, and the server does not shut down MySQL. To ensure that the server cannot accept updates when Group Replication did not start, we therefore recommend that

super_read_only=ON is set in the server's configuration file at startup, and then changed to OFF after Group Replication has been started successfully.

- group_replication_flow_control_applier_threshold

Property	Value
Command-Line Format	--group-replication-flow-control-applier-threshold=value
System Variable	group_replication_flow_control_applier_thresho
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	25000
Minimum Value	0
Maximum Value	2147483647

Specifies the number of waiting transactions in the applier queue that trigger flow control. This variable can be changed without resetting Group Replication.

- group_replication_flow_control_certifier_threshold

Property	Value
Command-Line Format	--group-replication-flow-control-certifier-threshold=value
System Variable	group_replication_flow_control_certifier_thres
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	25000
Minimum Value	0
Maximum Value	2147483647

Specifies the number of waiting transactions in the certifier queue that trigger flow control. This variable can be changed without resetting Group Replication.

- group_replication_flow_control_hold_percent

Property	Value
Command-Line Format	--group-replication-flow-control-hold-percent=value
Introduced	8.0.2
System Variable	group_replication_flow_control_hold_percent
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10

Property	Value
Minimum Value	`0`
Maximum Value	`100`

Defines what percentage of the group quota remains unused to allow a cluster under flow control to catch up on backlog. A value of 0 implies that no part of the quota is reserved for catching up on the work backlog.

- `group_replication_flow_control_max_commit_quota`

Property	Value
Command-Line Format	`--group-replication-flow-control-max-commit-quota=value`
Introduced	8.0.2
System Variable	`group_replication_flow_control_max_commit_q`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`0`
Minimum Value	`0`
Maximum Value	`2147483647`

Defines the maximum flow control quota of the group, or the maximum available quota for any period while flow control is enabled. A value of 0 implies that there is no maximum quota set. Cannot be smaller than `group_replication_flow_control_min_quota` and `group_replication_flow_control_min_recovery_quota`.

- `group_replication_flow_control_member_quota_percent`

Property	Value
Command-Line Format	`--group-replication-flow-control-member-quota-percent=value`
Introduced	8.0.2
System Variable	`group_replication_flow_control_member_quota`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`0`
Minimum Value	`0`
Maximum Value	`100`

Defines the percentage of the quota that a member should assume is available for itself when calculating the quotas. A value of 0 implies that the quota should be split equally between members that were writers in the last period.

- `group_replication_flow_control_min_quota`

Property	Value
Command-Line Format	`--group-replication-flow-control-min-quota=value`
Introduced	8.0.2
System Variable	`group_replication_flow_control_min_quota`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`0`
Minimum Value	`0`
Maximum Value	`2147483647`

Controls the lowest flow control quota that can be assigned to a member, independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. Cannot be larger than `group_replication_flow_control_max_commit_quota`.

- `group_replication_flow_control_min_recovery_quota`

Property	Value
Command-Line Format	`--group-replication-flow-control-min-recovery-quota=value`
Introduced	8.0.2
System Variable	`group_replication_flow_control_min_recovery_qu`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`0`
Minimum Value	`0`
Maximum Value	`2147483647`

Controls the lowest quota that can be assigned to a member because of another recovering member in the group, independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. Cannot be larger than `group_replication_flow_control_max_commit_quota`.

- `group_replication_flow_control_mode`

Property	Value
Command-Line Format	`--group-replication-flow-control-mode=value`
System Variable	`group_replication_flow_control_mode`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration

Property	Value
Default Value	`QUOTA`

Valid Values	`DISABLED`
	
	`QUOTA`

Specifies the mode used for flow control. This variable can be changed without resetting Group Replication.

- `group_replication_flow_control_period`

Property	Value
Command-Line Format	`--group-replication-flow-control-period=value`
Introduced	8.0.2
System Variable	`group_replication_flow_control_period`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`1`
Minimum Value	`1`
Maximum Value	`60`

Defines how many seconds to wait between flow control iterations, in which flow control messages are sent and flow control management tasks are run.

- `group_replication_flow_control_release_percent`

Property	Value
Command-Line Format	`--group-replication-flow-control-release-percent=value`
Introduced	8.0.2
System Variable	`group_replication_flow_control_release_perc`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`50`
Minimum Value	`0`
Maximum Value	`1000`

Defines how the group quota should be released when flow control no longer needs to throttle the writer members, with this percentage being the quota increase per flow control period. A value of 0 implies that once the flow control thresholds are within limits the quota is released in a single flow control iteration. The range allows the quota to be released at up to 10 times current quota, as that allows a greater degree of adaptation, mainly when the flow control period is large and the quotas are very small.

- `group_replication_force_members`

Property	Value
Command-Line Format	`--group-replication-force-members=value`
System Variable	`group_replication_force_members`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

A list of peer addresses as a comma separated list such as `host1:port1`,`host2:port2`. This option is used to force a new group membership, in which the excluded members do not receive a new view and are blocked.

You must specify the address or host name and port as they are given in the `group_replication_local_address` option for each member. An IPv6 address must be specified in square brackets. For example:

```
"198.51.100.44:33061,[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061,example.org:33061"
```

The group communication engine (XCom) checks that the supplied IP addresses are in a valid format, and checks that you have not included any group members that are currently unreachable. Otherwise, the new configuration is not validated, so you must be careful to include only online servers that are reachable members of the group. Any incorrect values or invalid host names in the list could cause the group to be blocked with an invalid configuration.

It is important before forcing a new membership configuration to ensure that the servers to be excluded have been shut down. If they are not, shut them down before proceeding. Group members that are still online can automatically form new configurations, and if this has already taken place, forcing a further new configuration could create an artificial split-brain situation for the group.

After you have used the `group_replication_force_members` system variable to successfully force a new group membership and unblock the group, ensure that you clear the system variable. `group_replication_force_members` must be empty in order to issue a `START GROUP_REPLICATION` statement.

For details of the procedure to follow, see Section 18.4.5, “Network Partitioning”.

- `group_replication_group_name`

Property	Value
Command-Line Format	`--group-replication-group-name=value`
System Variable	`group_replication_group_name`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The name of the group which this server instance belongs to. Must be a valid UUID. This UUID is used internally when setting GTIDs for Group Replication events in the binary log.

Important

A unique UUID must be used.

- `group_replication_group_seeds`

Property	Value
Command-Line Format	`--group-replication-group-seeds=value`
System Variable	`group_replication_group_seeds`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

A list of group members that provide a member which joins the group with the data required for the joining member to gain synchrony with the group. The list consists of a single internal network address or host name for each included seed member, as configured in the seed member's `group_replication_local_address` system variable (not the seed member's SQL hostname and port). The addresses of the seed members are specified as a comma separated list, such as `host1:port1`,`host2:port2`. An IPv6 address must be specified in square brackets. For example:

```
group_replication_group_seeds= "198.51.100.44:33061,[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061, exa
```

Note that the value you specify for this variable is not validated until a `START GROUP_REPLICATION` statement is issued and the Group Communication System (GCS) is available.

Usually this list consists of all members of the group, but you can choose a subset of the group members to be seeds. The list must contain at least one valid member address. Each address is validated when starting Group Replication. If the list does not contain any valid member addresses, issuing `START GROUP_REPLICATION` fails.

When a server is joining a replication group, it attempts to connect to the first seed member listed in its `group_replication_group_seeds` system variable. If the connection is refused, the joining member tries to connect to each of the other seed members in the list in order. If the joining member connects to a seed member but does not get added to the replication group as a result (for example, because the seed member does not have the joining member's address in its whitelist and closes the connection), the joining member continues to try the remaining seed members in the list in order.

A joining member must communicate with the seed member using the same protocol (IPv4 or IPv6) that the seed member advertises in the `group_replication_group_seeds` option. For the purpose of IP address whitelisting for Group Replication, the whitelist on the seed member must include an IP address for the joining member for the protocol offered by the seed member, or a host name that resolves to an address for that protocol. This address or host name must be set up and whitelisted in addition to the joining member's `group_replication_local_address` if the protocol for that address does not match the seed member's advertised protocol. If a joining member does not have a whitelisted address for the appropriate protocol, its connection attempt is refused. For more information, see Section 18.5.1, “IP Address Whitelisting”.

- `group_replication_gtid_assignment_block_size`

Property	Value
Command-Line Format	`--group-replication-gtid-assignment-block-size=value`
System Variable	`group_replication_gtid_assignment_block_siz`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No

Property	Value
Type	Integer
Default Value	`1000000`
Minimum Value	`1`
Maximum Value (64-bit platforms)	`9223372036854775807`
Maximum Value (32-bit platforms)	`4294967295`

The number of consecutive GTIDs that are reserved for each member. Each member consumes its blocks and reserves more when needed.

- `group_replication_ip_whitelist`

Property	Value
Command-Line Format	`--group-replication-ip-whitelist=value`
System Variable	`group_replication_ip_whitelist`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	`AUTOMATIC`

Specifies which hosts are permitted to connect to the group. The address that you specify for each group member in `group_replication_local_address` must be whitelisted on the other servers in the replication group. Note that the value you specify for this variable is not validated until a `START GROUP_REPLICATION` statement is issued and the Group Communication System (GCS) is available.

By default, this system variable is set to `AUTOMATIC`, which permits connections from private subnetworks active on the host. The group communication engine (XCom) automatically scans active interfaces on the host, and identifies those with addresses on private subnetworks. These addresses and the `localhost` IP address for IPv4 and (from MySQL 8.0.14) IPv6 are used to create the Group Replication whitelist. For a list of the ranges from which addresses are automatically whitelisted, see Section 18.5.1, “IP Address Whitelisting”.

The automatic whitelist of private addresses cannot be used for connections from servers outside the private network. For Group Replication connections between server instances that are on different machines, you must provide public IP addresses and specify these as an explicit whitelist. If you specify any entries for the whitelist, the private and `localhost` addresses are not added automatically, so if you use any of these, you must specify them explicitly.

As the value of the `group_replication_ip_whitelist` option, you can specify any combination of the following:

- IPv4 addresses (for example, `198.51.100.44`)
- IPv4 addresses with CIDR notation (for example, `192.0.2.21/24`)
- IPv6 addresses, from MySQL 8.0.14 (for example, `2001:db8:85a3:8d3:1319:8a2e:370:7348`)
- IPv6 addresses with CIDR notation, from MySQL 8.0.14 (for example, `2001:db8:85a3:8d3::/64`)
- Host names (for example, `example.org`)

- Host names with CIDR notation (for example, `www.example.com/24`)

Before MySQL 8.0.14, host names could only resolve to IPv4 addresses. From MySQL 8.0.14, host names can resolve to IPv4 addresses, IPv6 addresses, or both. If a host name resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. You can use CIDR notation in combination with host names or IP addresses to whitelist a block of IP addresses with a particular network prefix, but do ensure that all the IP addresses in the specified subnet are under your control.

A comma must separate each entry in the whitelist. For example:

```
"192.0.2.21/24,198.51.100.44,203.0.113.0/24,2001:db8:85a3:8d3:1319:8a2e:370:7348,example.org,www.exam
```

If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 `group_replication_local_address`, or the reverse, you must also set up and whitelist an alternative address for the joining member for the protocol offered by the seed member (or a host name that resolves to an address for that protocol). For more information, see Section 18.5.1, “IP Address Whitelisting”.

It is possible to configure different whitelists on different group members according to your security requirements, for example, in order to keep different subnets separate. However, this can cause issues when a group is reconfigured. If you do not have a specific security requirement to do otherwise, use the same whitelist on all members of a group. For more details, see Section 18.5.1, “IP Address Whitelisting”.

For host names, name resolution takes place only when a connection request is made by another server. A host name that cannot be resolved is not considered for whitelist validation, and a warning message is written to the error log. Forward-confirmed reverse DNS (FCrDNS) verification is carried out for resolved host names.

Warning

Host names are inherently less secure than IP addresses in a whitelist. FCrDNS verification provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your whitelist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

- `group_replication_local_address`

Property	Value
Command-Line Format	`--group-replication-local-address=value`
System Variable	`group_replication_local_address`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The network address which the member provides for connections from other members, specified as a `host:port` formatted string. This address must be reachable by all members of the group because it is used by the group communication engine (XCom, a Paxos variant) for TCP

communication between remote XCom instances. Communication with the local instance is over an input channel using shared memory.

Warning

Do not use this address for communication with the member. This is not the MySQL server SQL protocol host and port.

The address or host name that you specify in `group_replication_local_address` is used by Group Replication as the unique identifier for a group member within the replication group. You can use the same port for all members of a replication group as long as the host names or IP addresses are all different, and you can use the same host name or IP address for all members as long as the ports are all different. The recommended port for `group_replication_local_address` is 33061. Note that the value you specify for this variable is not validated until the `START GROUP_REPLICATION` statement is issued and the Group Communication System (GCS) is available.

The network address configured by `group_replication_local_address` must be resolvable by all group members. For example, if each server instance is on a different machine with a fixed network address, you could use the IP address of the machine, such as 10.0.0.1. If you use a host name, you must use a fully qualified name, and ensure it is resolvable through DNS, correctly configured `/etc/hosts` files, or other name resolution processes. From MySQL 8.0.14, IPv6 addresses (or host names that resolve to them) can be used as well as IPv4 addresses. An IPv6 address must be specified in square brackets in order to distinguish the port number, for example:

```
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

If a host name specified as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. For more information on Group Replication support for IPv6 networks and on replication groups with a mix of members using IPv4 and members using IPv6, see Section 18.4.6, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”.

For the purpose of IP address whitelisting for Group Replication, the address that you specify for each group member in `group_replication_local_address` must be added to the list for the `group_replication_ip_whitelist` option on the other servers in the replication group. If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when this member has an IPv4 `group_replication_local_address`, or the reverse, you must also set up and whitelist an alternative address for this member for the required protocol (or a host name that resolves to an address for that protocol). For more information, see Section 18.5.1, “IP Address Whitelisting”.

- `group_replication_member_weight`

Property	Value
Command-Line Format	`--group-replication-member-weight=value`
Introduced	8.0.2
System Variable	`group_replication_member_weight`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`50`
Minimum Value	`0`

Property	Value
Maximum Value	`100`

A percentage weight that can be assigned to members to influence the chance of the member being elected as primary in the event of failover, for example when the existing primary leaves a single-primary group. Assign numeric weights to members to ensure that specific members are elected, for example during scheduled maintenance of the primary or to ensure certain hardware is prioritized in the event of failover.

For a group with members configured as follows:

- `member-1`: group_replication_member_weight=30, server_uuid=aaaa
- `member-2`: group_replication_member_weight=40, server_uuid=bbbb
- `member-3`: group_replication_member_weight=40, server_uuid=cccc
- `member-4`: group_replication_member_weight=40, server_uuid=dddd

during election of a new primary the members above would be sorted as `member-2`, `member-3`, `member-4`, and `member-1`. This results in `member`-2 being chosen as the new primary in the event of failover. For more information, see Section 18.4.1.1, “Single-Primary Mode”.

- `group_replication_member_expel_timeout`

Property	Value
Command-Line Format	`--group-replication-member-expel-timeout=value`
Introduced	8.0.13
System Variable	`group_replication_member_expel_timeout`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`0`
Minimum Value	`0`
Maximum Value (>= 8.0.14)	`3600`
Maximum Value (<= 8.0.13)	`31536000`

The period of time in seconds that a Group Replication group member waits after creating a suspicion before expelling from the group the member suspected of having failed. The initial 5-second detection period before a suspicion is created does not count as part of this time. Changing the value of `group_replication_member_expel_timeout` on a group member takes effect immediately for existing as well as future suspicions on that group member. It is not mandatory for all members of a group to have the same setting, but it is recommended in order to avoid unexpected expulsions.

A group member is expelled when another member's suspicion of it (or its own suspicion of itself) times out. By default, `group_replication_member_expel_timeout` is set to 0, meaning that there is no waiting period and a suspected member is liable for expulsion immediately after the 5-second detection period ends. An additional short period of time might elapse before the expelling mechanism detects and implements the expulsion. If a group member is at an older MySQL Server version that does not support this setting, this is its behavior towards other members or itself.

To avoid unnecessary expulsions on slower networks, or in the case of expected transient network failures or machine slowdowns, you can specify a timeout value greater than zero, up to a maximum of 3600 seconds (1 hour). If a suspect member becomes active again before the suspicion times out, it rejoins the group, applies all the messages that were buffered by the remaining group members, and enters `ONLINE` state. Otherwise, it is liable for expulsion immediately after the suspicion times out. For alternative mitigation strategies to avoid unnecessary expulsions where this system variable is not available, see Section 18.9.2, "Group Replication Limitations".

The waiting period before expelling a member only applies to members that have previously been active in the group. Non-members that were never active in the group do not get this waiting period and are removed after the initial detection period because they took too long to join.

When a member is expelled, if it has the `group_replication_autorejoin_tries` system variable set to specify a number of auto-rejoin attempts, it proceeds to make the specified number of attempts to rejoin the group while in super read only mode. If the member does not have any auto-rejoin attempts specified, or if it has exhausted the specified number of attempts, it follows the action specified by the system variable `group_replication_exit_state_action`, which can be to remain online but in super read only mode, or shut down MySQL. For more information on using these options to configure member behavior in failure detection situations, see Section 18.6.6, "Responses to Failure Detection and Network Partitioning".

If any members in a group are currently under suspicion, the group membership cannot be reconfigured (by adding or removing members or electing a new leader). If group membership changes need to be implemented while one or more members are under suspicion, and you want the suspect members to remain in the group, take any actions required to make the members active again, if that is possible. If you cannot make the members active again and you want them to be expelled from the group, you can force the suspicions to time out immediately. Do this by changing the value of `group_replication_member_expel_timeout` on any active members to a value lower than the time that has already elapsed since the suspicions were created. The suspect members then become liable for expulsion immediately.

- `group_replication_message_cache_size`

Property	Value
Command-Line Format	`--group-replication-message-cache-size=value`
Introduced	8.0.16
System Variable	`group_replication_message_cache_size`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`1073741824 (1 GB)`
Minimum Value	`1073741824 (1 GB)`
Maximum Value (64-bit platforms)	`18446744073709551615 (16 EiB)`
Maximum Value (32-bit platforms)	`315360004294967295 (4 GB)`

The maximum amount of memory that is available for the message cache in the group communication engine (XCom), which holds messages (and their metadata) that are exchanged between the group members as a part of the consensus protocol. Among other functions, the message cache is used for recovery by members that return to the group after a period where they were unable to communicate with the other group members. The `group_replication_member_expel_timeout` system variable determines the time (up to

an hour) allowed for members to return to the group rather than being expelled. The size of the message cache should be set with reference to the expected volume of messages in this time period, so that it contains all the missed messages required for members to return successfully.

`group_replication_message_cache_size` has a default and minimum setting of 1073741824 bytes (1 GB). It is advisable (though not required) to set the same cache size limit on all group members, because a rejoining member selects any other member at random for recovery of missed messages. Ensure that sufficient memory is available on your system for your chosen cache size limit, considering the size of MySQL Server's other caches and object pools.

The cache size limit can be increased or reduced dynamically at runtime. If you reduce the cache size limit, XCom removes the oldest entries that have been decided and delivered until the current size is below the limit. The Group Communication System (GCS) alerts you, by a warning message, when a message that is likely to be needed for recovery by a member that is currently unreachable is removed from the message cache. For more information on tuning the message cache size, see Section 18.6.5, “XCom Cache Management”.

- `group_replication_poll_spin_loops`

Property	Value
Command-Line Format	`--group-replication-poll-spin-loops=value`
System Variable	`group_replication_poll_spin_loops`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`0`
Minimum Value	`0`
Maximum Value (64-bit platforms)	`18446744073709551615`
Maximum Value (32-bit platforms)	`4294967295`

The number of times the group communication thread waits for the communication engine mutex to be released before the thread waits for more incoming network messages.

- `group_replication_recovery_complete_at`

Property	Value
Command-Line Format	`--group-replication-recovery-complete-at=value`
System Variable	`group_replication_recovery_complete_at`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	`TRANSACTIONS_APPLIED`
Valid Values	`TRANSACTIONS_CERTIFIED` `TRANSACTIONS_APPLIED`

Recovery policies when handling cached transactions after state transfer. This option specifies whether a member is marked online after it has received all transactions that it missed before

it joined the group (TRANSACTIONS_CERTIFIED) or after it has received and applied them (TRANSACTIONS_APPLIED).

- group_replication_recovery_get_public_key

Property	Value
Command-Line Format	--group-replication-recovery-get-public-key
Introduced	8.0.4
System Variable	group_replication_recovery_get_public_key
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether to request from the master the public key required for RSA key pair-based password exchange. This variable applies to slaves that authenticate with the caching_sha2_password authentication plugin. For that plugin, the master does not send the public key unless requested.

If group_replication_recovery_public_key_path is set to a valid public key file, it takes precedence over group_replication_recovery_get_public_key.

- group_replication_recovery_public_key_path

Property	Value
Command-Line Format	--group-replication-recovery-public-key-path
Introduced	8.0.4
System Variable	group_replication_recovery_public_key_path
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name
Default Value	NULL

The path name to a file containing a slave-side copy of the public key required by the master for RSA key pair-based password exchange. The file must be in PEM format. This variable applies to slaves that authenticate with the sha256_password or caching_sha2_password authentication plugin. (For sha256_password, setting group_replication_recovery_public_key_path applies only if MySQL was built using OpenSSL.)

If group_replication_recovery_public_key_path is set to a valid public key file, it takes precedence over group_replication_recovery_get_public_key.

- group_replication_recovery_reconnect_interval

Property	Value
Command-Line Format	--group-replication-recovery-reconnect-interval=value
System Variable	group_replication_recovery_reconnect_interval
Scope	Global

Property	Value
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	0
Maximum Value	31536000

The sleep time, in seconds, between reconnection attempts when no donor was found in the group.

- group_replication_recovery_retry_count

Property	Value
Command-Line Format	--group-replication-recovery-retry-count=value
System Variable	group_replication_recovery_retry_count
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	31536000

The number of times that the member that is joining tries to connect to the available donors before giving up.

- group_replication_recovery_ssl_ca

Property	Value
Command-Line Format	--group-replication-recovery-ssl-ca=value
System Variable	group_replication_recovery_ssl_ca
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The path to a file that contains a list of trusted SSL certificate authorities.

- group_replication_recovery_ssl_capath

Property	Value
Command-Line Format	--group-replication-recovery-ssl-capath=value
System Variable	group_replication_recovery_ssl_capath
Scope	Global
Dynamic	Yes

Property	Value
SET_VAR Hint Applies	No
Type	String

The path to a directory that contains trusted SSL certificate authority certificates.

- `group_replication_recovery_ssl_cert`

Property	Value
Command-Line Format	`--group-replication-recovery-ssl-cert=value`
System Variable	`group_replication_recovery_ssl_cert`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The name of the SSL certificate file to use for establishing a secure connection.

- `group_replication_recovery_ssl_cipher`

Property	Value
Command-Line Format	`--group-replication-recovery-ssl-cipher=value`
System Variable	`group_replication_recovery_ssl_cipher`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The list of permitted ciphers for SSL encryption.

- `group_replication_recovery_ssl_crl`

Property	Value
Command-Line Format	`--group-replication-recovery-ssl-crl=value`
System Variable	`group_replication_recovery_ssl_crl`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name

The path to a directory that contains files containing certificate revocation lists.

- `group_replication_recovery_ssl_crlpath`

Property	Value
Command-Line Format	`--group-replication-recovery-ssl-crlpath=value`

Property	Value
System Variable	group_replication_recovery_ssl_crlpath
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Directory name

The path to a directory that contains files containing certificate revocation lists.

- group_replication_recovery_ssl_key

Property	Value
Command-Line Format	--group-replication-recovery-ssl-key=value
System Variable	group_replication_recovery_ssl_key
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

The name of the SSL key file to use for establishing a secure connection.

- group_replication_recovery_ssl_verify_server_cert

Property	Value
Command-Line Format	--group-replication-recovery-ssl-verify-server-cert=value
System Variable	group_replication_recovery_ssl_verify_serve
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Make the recovery process check the server's Common Name value in the donor sent certificate.

- group_replication_recovery_use_ssl

Property	Value
Command-Line Format	--group-replication-recovery-use-ssl=value
System Variable	group_replication_recovery_use_ssl
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether Group Replication recovery connection should use SSL or not.

- `group_replication_single_primary_mode`

Property	Value
Command-Line Format	`--group-replication-single-primary-mode=value`
System Variable	`group_replication_single_primary_mode`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	`ON`

Instructs the group to automatically pick a single server to be the one that handles read/write workload. This server is the PRIMARY and all others are SECONDARIES.

- `group_replication_ssl_mode`

Property	Value
Command-Line Format	`--group-replication-ssl-mode=value`
System Variable	`group_replication_ssl_mode`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	`DISABLED`

Valid Values	`DISABLED`
	`REQUIRED`
	`VERIFY_CA`
	`VERIFY_IDENTITY`

Specifies the security state of the connection between Group Replication members.

- `group_replication_start_on_boot`

Property	Value
Command-Line Format	`--group-replication-start-on-boot=value`
System Variable	`group_replication_start_on_boot`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	`ON`

Whether the server should start Group Replication or not during server start.

- `group_replication_transaction_size_limit`

Property	Value
Command-Line Format	`--group-replication-transaction-size-limit=value`
System Variable	`group_replication_transaction_size_limit`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value (>= 8.0.2)	`150000000`
Default Value (<= 8.0.1)	`0`
Minimum Value	`0`
Maximum Value	`2147483647`

Configures the maximum transaction size in bytes which the replication group accepts. Transactions larger than this size are rolled back by the receiving member and are not broadcast to the group. Large transactions can cause problems for a replication group in terms of memory allocation, which can cause the system to slow down, or in terms of network bandwidth consumption, which can cause a member to be suspected of having failed because it is busy processing the large transaction.

When this system variable is set to 0 there is no limit to the size of transactions the group accepts. From MySQL 8.0, the default setting for this system variable is 150000000 bytes (approximately 143 MB). Adjust the value of this system variable depending on the maximum message size that you need the group to tolerate, bearing in mind that the time taken to process a transaction is proportional to its size. For further mitigation strategies, see Section 18.9.2, “Group Replication Limitations”.

- `group_replication_unreachable_majority_timeout`

Property	Value
Command-Line Format	`--group-replication-unreachable-majority-timeout=value`
Introduced	8.0.2
System Variable	`group_replication_unreachable_majority_time`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`0`
Minimum Value	`0`
Maximum Value	`31536000`

Configures how long members that suffer a network partition and cannot connect to the majority wait before leaving the group.

In a group of 5 servers (S1,S2,S3,S4,S5), if there is a disconnection between (S1,S2) and (S3,S4,S5) there is a network partition. The first group (S1,S2) is now in a minority because it cannot contact more than half of the group. While the majority group (S3,S4,S5) remains running, the minority group waits for the specified time for a network reconnection. Any transactions processed by the minority group are blocked until Group Replication is stopped using `STOP GROUP REPLICATION` on the members of the minority. Note that

`group_replication_unreachable_majority_timeout` has no effect if it is set on the servers in the minority group after the loss of majority has been detected.

By default, this system variable is set to 0, which means that members that find themselves in a minority due to a network partition wait forever to leave the group. If configured to a number of seconds, members wait for this amount of time after losing contact with the majority of members before leaving the group. When the specified time elapses, all pending transactions processed by the minority are rolled back, and the servers in the minority partition move to the ERROR state. If a member has the `group_replication_autorejoin_tries` system variable set to specify a number of auto-rejoin attempts, it proceeds to make the specified number of attempts to rejoin the group while in super read only mode. If the member does not have any auto-rejoin attempts specified, or if it has exhausted the specified number of attempts, it follows the action specified by the system variable `group_replication_exit_state_action`, which can be to remain in super read only mode or shut down MySQL. For more information on using these options to configure member behavior in failure detection situations, see Section 18.6.6, “Responses to Failure Detection and Network Partitioning”.

Warning

When you have a symmetric group, with just two members for example (S0,S2), if there is a network partition and there is no majority, after the configured timeout all members enter `ERROR` state.

Group Replication Status Variable

This section describes the status variables which provide information about Group Replication. The variable has the following meaning:

- `group_replication_primary_member`

  Shows the primary member's UUID when the group is operating in single-primary mode. If the group is operating in multi-primary mode, shows an empty string.

  Warning

  The `group_replication_primary_member` status variable has been deprecated and is scheduled to be removed in a future version.

  See Section 18.4.1.3, “Finding the Primary”.

18.9 Requirements and Limitations

This section lists and explains the requirements and limitations of Group Replication.

18.9.1 Group Replication Requirements

Server instances that you want to use for Group Replication must satisfy the following requirements.

Infrastructure

- **InnoDB Storage Engine.** Data must be stored in the `InnoDB` transactional storage engine. Transactions are executed optimistically and then, at commit time, are checked for conflicts. If there are conflicts, in order to maintain consistency across the group, some transactions are rolled back. This means that a transactional storage engine is required. Moreover, `InnoDB` provides some additional functionality that enables better management and handling of conflicts when operating together with Group Replication.

- **Primary Keys.** Every table that is to be replicated by the group must have a defined primary key, or primary key equivalent where the equivalent is a non-null unique key. Such keys are required as a unique identifier for every row within a table, enabling the system to determine which transactions conflict by identifying exactly which rows each transaction has modified.

- **Network Performance.** MySQL Group Replication is designed to be deployed in a cluster environment where server instances are very close to each other. The performance and stabiity of a group can be impacted by both network latency and network bandwidth. Bi-directional communication must be maintained at all times between all group members. If either inbound or outbound communication is blocked for a server instance (for example, by a firewall, or by connectivity issues), the member cannot function in the group, and the group members (including the member with issues) might not be able to report the correct member status for the affected server instance.

  From MySQL 8.0.14, you can use an IPv4 or IPv6 network infrastructure, or a mix of the two, for TCP communication between remote Group Replication servers. There is also nothing preventing Group Replication from operating over a virtual private network (VPN).

  Also from MySQL 8.0.14, where Group Replication server instances are co-located and share a local group communication engine (XCom) instance, a dedicated input channel with lower overhead is used for communication where possible instead of the TCP socket. For certain Group Replication tasks that require communication between remote XCom instances, such as joining a group, the TCP network is still used, so network performance influences the group's performance.

Server Instance Configuration

The following options must be configured on server instances that are members of a group.

- **Binary Log Active.** Set `--log-bin[=log_file_name]`. MySQL Group Replication replicates binary log contents, therefore the binary log needs to be on for it to operate. This option is enabled by default. See Section 5.4.4, “The Binary Log”.

- **Slave Updates Logged.** Set `--log-slave-updates`. Servers need to log binary logs that are applied through the replication applier. Servers in the group need to log all transactions that they receive and apply from the group. This is required because recovery is conducted by relying on binary logs form participants in the group. Therefore, copies of each transaction need to exist on every server, even for those transactions that were not initiated on the server itself. This option is enabled by default.

- **Binary Log Row Format.** Set `--binlog-format=row`. Group Replication relies on row-based replication format to propagate changes consistently among the servers in the group. It relies on row-based infrastructure to be able to extract the necessary information to detect conflicts among transactions that execute concurrently in different servers in the group. See Section 17.2.1, “Replication Formats”.

- **Global Transaction Identifiers On.** Set `--gtid-mode=ON`. Group Replication uses global transaction identifiers to track exactly which transactions have been committed on every server instance and thus be able to infer which servers have executed transactions that could conflict with already committed transactions elsewhere. In other words, explicit transaction identifiers are a fundamental part of the framework to be able to determine which transactions may conflict. See Section 17.1.3, “Replication with Global Transaction Identifiers”.

- **Replication Information Repositories.** Set `--master-info-repository=TABLE` and `--relay-log-info-repository=TABLE`. The replication applier needs to have the master information and relay log metadata written to the `mysql.slave_master_info` and `mysql.slave_relay_log_info` system tables. This ensures the Group Replication plugin has consistent recoverability and transactional management of the replication metadata. From MySQL 8.0.2, these options are set to `TABLE` by default, and from MySQL 8.0.3, the `FILE` setting is deprecated. See Section 17.2.4.2, “Slave Status Logs”.

- **Transaction Write Set Extraction.** Set `--transaction-write-set-extraction=XXHASH64` so that while collecting rows to log them to the binary log, the server collects the write set as well. The write set is based on the primary keys of each row and is a simplified and compact view of a tag that uniquely identifies the row that was changed. This tag is then used for detecting conflicts. This option is enabled by default.

- **Multithreaded Appliers.** Group Replication members can be configured as multithreaded slaves, enabling transactions to be applied in parallel. A nonzero value for `slave_parallel_workers` enables the multithreaded applier on the member, and up to 1024 parallel applier threads can be specified. Setting `slave_preserve_commit_order=1` ensures that the final commit of parallel transactions is in the same order as the original transactions, as required for Group Replication, which relies on consistency mechanisms built around the guarantee that all participating members receive and apply committed transaction in the same order. Finally, the setting `slave_parallel_type=LOGICAL_CLOCK`, which specifies the policy used to decide which transactions are allowed to execute in parallel on the slave, is required with `slave_preserve_commit_order=1`. Setting `slave_parallel_workers=0` disables parallel execution and gives the slave a single applier thread and no coordinator thread. With that setting, the `slave_parallel_type` and `slave_preserve_commit_order` options have no effect and are ignored.

18.9.2 Group Replication Limitations

The following known limitations exist for Group Replication. Note that the limitations and issues described for multi-primary mode groups can also apply in single-primary mode clusters during a failover event, while the newly elected primary flushes out its applier queue from the old primary.

Tip

Group Replication is built on GTID based replication, therefore you should also be aware of Section 17.1.3.6, “Restrictions on Replication with GTIDs”.

- **Replication Event Checksums.** Due to a design limitation of replication event checksums, Group Replication cannot currently make use of them. Therefore set `--binlog-checksum=NONE`.

- **Gap Locks.** The certification process does not take into account gap locks, as information about gap locks is not available outside of `InnoDB`. See Gap Locks for more information.

Note

Unless you rely on `REPEATABLE READ` semantics in your applications, we recommend using the `READ COMMITTED` isolation level with Group Replication. InnoDB does not use gap locks in `READ COMMITTED`, which aligns the local conflict detection within InnoDB with the distributed conflict detection performed by Group Replication.

- **Table Locks and Named Locks.** The certification process does not take into account table locks (see Section 13.3.6, “LOCK TABLES and UNLOCK TABLES Syntax”) or named locks (see `GET_LOCK()`).

- **SERIALIZABLE Isolation Level.** `SERIALIZABLE` isolation level is not supported in multi-primary groups by default. Setting a transaction isolation level to `SERIALIZABLE` configures Group Replication to refuse to commit the transaction.

- **Concurrent DDL versus DML Operations.** Concurrent data definition statements and data manipulation statements executing against the same object but on different servers is not supported when using multi-primary mode. During execution of Data Definition Language (DDL) statements on an object, executing concurrent Data Manipulation Language (DML) on the same object but on a different server instance has the risk of conflicting DDL executing on different instances not being detected.

- **Foreign Keys with Cascading Constraints.** Multi-primary mode groups (members all configured with `group_replication_single_primary_mode=OFF`) do not support tables with multi-level foreign key dependencies, specifically tables that have defined `CASCADING` foreign key constraints. This is because foreign key constraints that result in cascading operations executed by a multi-primary mode group can result in undetected conflicts and lead to inconsistent data across the members of the group. Therefore we recommend setting

`group_replication_enforce_update_everywhere_checks=ON` on server instances used in multi-primary mode groups to avoid undetected conflicts.

In single-primary mode this is not a problem as it does not allow concurrent writes to multiple members of the group and thus there is no risk of undetected conflicts.

- **Very Large Transactions.** If an individual transaction results in GTID contents which are large enough that the message cannot be copied between group members over the network within a 5-second window, members can be suspected of having failed, and then expelled, just because they are busy processing the transaction. Large transactions can also cause the system to slow due to problems with memory allocation. To avoid these issues use the following mitigations:

  - Where possible, try and limit the size of your transactions. For example, split up files used with `LOAD DATA` into smaller chunks.

  - Use the system variable `group_replication_transaction_size_limit` to specify a maximum transaction size that the group will accept. Transactions above this size are rolled back and are not sent to the group. In MySQL 8.0, this system variable defaults to a maximum transaction size of 150000000 bytes (approximately 143 MB). Adjust the value of this variable depending on the maximum message size that you need the group to tolerate, bearing in mind that the time taken to process a transaction is proportional to its size.

  - From MySQL 8.0.13, you can use the system variable `group_replication_member_expel_timeout` to allow additional time before a member under suspicion of having failed is expelled. You can allow up to an hour after the initial 5-second detection period before a suspect member is expelled from the group.

  - From MySQL 8.0.16, large messages are automatically fragmented, meaning that the 5-second detection period for raising a suspicion should not be triggered by a large message, unless there are other network issues at that time. In order for a replication group to use fragmentation, all group members must be at MySQL 8.0.16 or above, and the Group Replication communication protocol version in use by the group must allow fragmentation. You can use the system variable `group_replication_communication_max_message_size` to adjust the maximum message size, which defaults to 10485760 bytes (10 MiB), or to switch off fragmentation by specifying a zero value. For more information, see Section 18.6.4, “Message Fragmentation”.

- **Multi-primary Mode Deadlock.** When a group is operating in multi-primary mode, `SELECT .. FOR UPDATE` statements can result in a deadlock. This is because the lock is not shared across the members of the group, therefore the expectation for such a statement might not be reached.

- **Replication Filters.** Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replication slave to a master that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

- **Encrypted Connections.** Support for the TLSv1.3 protocol is available in MySQL Server as of MySQL 8.0.16, and requires compiling MySQL using OpenSSL 1.1.1 or higher. Group Replication does not currently support TLSv1.3, and if the server was compiled with this support, it is explicitly disabled in the group communication engine.

18.10 Frequently Asked Questions

This section provides answers to frequently asked questions.

What is the maximum number of MySQL servers in a group?

A group can consist of maximum 9 servers. Attempting to add another server to a group with 9 members causes the request to join to be refused.

How are servers in a group connected?

Servers in a group connect to the other servers in the group by opening a peer-to-peer TCP connection. These connections are only used for internal communication and message passing between servers in the group. This address is configured by the `group_replication_local_address` variable.

What is the group_replication_bootstrap_group option used for?

The bootstrap flag instructs a member to *create* a group and act as the initial seed server. The second member joining the group needs to ask the member that bootstrapped the group to dynamically change the configuration in order for it to be added to the group.

A member needs to bootstrap the group in two scenarios. When the group is originally created, or when shutting down and restarting the entire group.

How do I set credentials for the recovery procedure?

You pre-configure the Group Replication recovery channel credentials using the `CHANGE MASTER TO` statement.

Can I scale-out my write-load using Group Replication?

Not directly, but MySQL Group replication is a shared nothing full replication solution, where all servers in the group replicate the same amount of data. Therefore if one member in the group writes N bytes to storage as the result of a transaction commit operation, then roughly N bytes are written to storage on other members as well, because the transaction is replicated everywhere.

However, given that other members do not have to do the same amount of processing that the original member had to do when it originally executed the transaction, they apply the changes faster. Transactions are replicated in a format that is used to apply row transformations only, without having to re-execute transactions again (row-based format).

Furthermore, given that changes are propagated and applied in row-based format, this means that they are received in an optimized and compact format, and likely reducing the number of IO operations required when compared to the originating member.

To summarize, you can scale-out processing, by spreading conflict free transactions throughout different members in the group. And you can likely scale-out a small fraction of your IO operations, since remote servers receive only the necessary changes to read-modify-write changes to stable storage.

Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?

Some additional load is expected because servers need to be constantly interacting with each other for synchronization purposes. It is difficult to quantify how much more data. It also depends on the size of the group (three servers puts less stress on the bandwidth requirements than nine servers in the group).

Also the memory and CPU footprint are larger, because more complex work is done for the server synchronization part and for the group messaging.

Can I deploy Group Replication across wide-area networks?

Yes, but the network connection between each member *must* be reliable and have suitable perfomance. Low latency, high bandwidth network connections are a requirement for optimal performance.

If network bandwidth alone is an issue, then Section 18.6.3, “Message Compression” can be used to lower the bandwidth required. However, if the network drops packets, leading to re-transmissions and higher end-to-end latency, throughput and latency are both negatively affected.

Warning

When the network round-trip time (RTT) between any group members is 2 seconds or more you could encounter problems as the built-in failure detection mechanism could be incorrectly triggered.

Do members automatically rejoin a group in case of temporary connectivity problems?

This depends on the reason for the connectivity problem. If the connectivity problem is transient and the reconnection is quick enough that the failure detector is not aware of it, then the server may not be removed from the group. If it is a "long" connectivity problem, then the failure detector eventually suspects a problem and the server is removed from the group.

Once a server is removed from the group, you need to join it back again. In other words, after a server is removed explicitly from the group you need to rejoin it manually (or have a script doing it automatically).

When is a member excluded from a group?

If the member becomes silent, the other members remove it from the group configuration. In practice this may happen when the member has crashed or there is a network disconnection.

The failure is detected after a given timeout elapses for a given member and a new configuration without the silent member in it is created.

What happens when one node is significantly lagging behind?

There is no method for defining policies for when to expel members automatically from the group. You need to find out why a member is lagging behind and fix that or remove the member from the group. Otherwise, if the server is so slow that it triggers the flow control, then the entire group slows down as well. The flow control can be configured according to the your needs.

Upon suspicion of a problem in the group, is there a special member responsible for triggering a reconfiguration?

No, there is no special member in the group in charge of triggering a reconfiguration.

Any member can suspect that there is a problem. All members need to (automatically) agree that a given member has failed. One member is in charge of expelling it from the group, by triggering a reconfiguration. Which member is responsible for expelling the member is not something you can control or set.

Can I use Group Replication for sharding?

Group Replication is designed to provide highly available replica sets; data and writes are duplicated on each member in the group. For scaling beyond what a single system can provide, you need an orchestration and sharding framework built around a number of Group Replication sets, where each replica set maintains and manages a given shard or partition of your total dataset. This type of setup, often called a “sharded cluster”, allows you to scale reads and writes linearly and without limit.

How do I use Group Replication with SELinux?

If SELinux is enabled, which you can verify using `sestatus -v`, then you need to enable the use of the Group Replication communication port, configured by `group_replication_local_address`,

for `mysqld` so that it can bind to it and listen there. To see which ports MySQL is currently allowed to use, issue `semanage port -l | grep mysqld`. Assuming the port configured is 33061, add the necessary port to those permitted by SELinux by issuing `semanage port -a -t mysqld_port_t -p tcp 33061`.

How do I use Group Replication with iptables?

If `iptables` is enabled, then you need to open up the Group Replication port for communication between the machines. To see the current rules in place on each machine, issue `iptables -L`. Assuming the port configured is 33061, enable communication over the necessary port by issuing `iptables -A INPUT -p tcp --dport 33061 -j ACCEPT`.

How do I recover the relay log for a replication channel used by a group member?

The replication channels used by Group Replication behave in the same way as replication channels used in master to slave replication, and as such rely on the relay log. In the event of a change of the `relay_log` variable, or when the option is not set and the host name changes, there is a chance of errors. See Section 17.2.4.1, "The Slave Relay Log" for a recovery procedure in this situation. Alternatively, another way of fixing the issue specifically in Group Replication is to issue a `STOP GROUP_REPLICATION` statement and then a `START GROUP_REPLICATION` statement to restart the instance. The Group Replication plugin creates the `group_replication_applier` channel again.

Why does Group Replication use two bind addresses?

Group Replication uses two bind addresses in order to split network traffic between the SQL address, used by clients to communicate with the member, and the `group_replication_local_address`, used internally by the group members to communicate. For example, assume a server with two network interfaces assigned to the network addresses `203.0.113.1` and `198.51.100.179`. In such a situation you could use `203.0.113.1:33061` for the internal group network address by setting `group_replication_local_address=203.0.113.1:33061`. Then you could use `198.51.100.179` for `hostname` and `3306` for the `port`. Client SQL applications would then connect to the member at `198.51.100.179:3306`. This enables you to configure different rules on the different networks. Similarly, the internal group communication can be separated from the network connection used for client applications, for increased security.

How does Group Replication use network addresses and hostnames?

Group Replication uses network connections between members and therefore its functionality is directly impacted by how you configure hostnames and ports. For example, the Group Replication recovery procedure is based on asynchronous replication which uses the server's hostname and port. When a member joins a group it receives the group membership information, using the network address information that is listed at `performance_schema.replication_group_members`. One of the members listed in that table is selected as the donor of the missing data from the group to the new member.

This means that any value you configure using a hostname, such as the SQL network address or the group seeds address, must be a fully qualified name and resolvable by each member of the group. You can ensure this for example through DNS, or correctly configured `/etc/hosts` files, or other local processes. If a you want to configure the `MEMBER_HOST` value on a server, specify it using the `--report-host` option on the server before joining it to the group.

Important

The assigned value is used directly and is not affected by the `--skip-name-resolve` option.

To configure `MEMBER_PORT` on a server, specify it using the `--report-port` option.

How do I find the primary?

If the group is operating in single-primary mode, it can be useful to find out which member is the primary. See Section 18.4.1.3, “Finding the Primary”

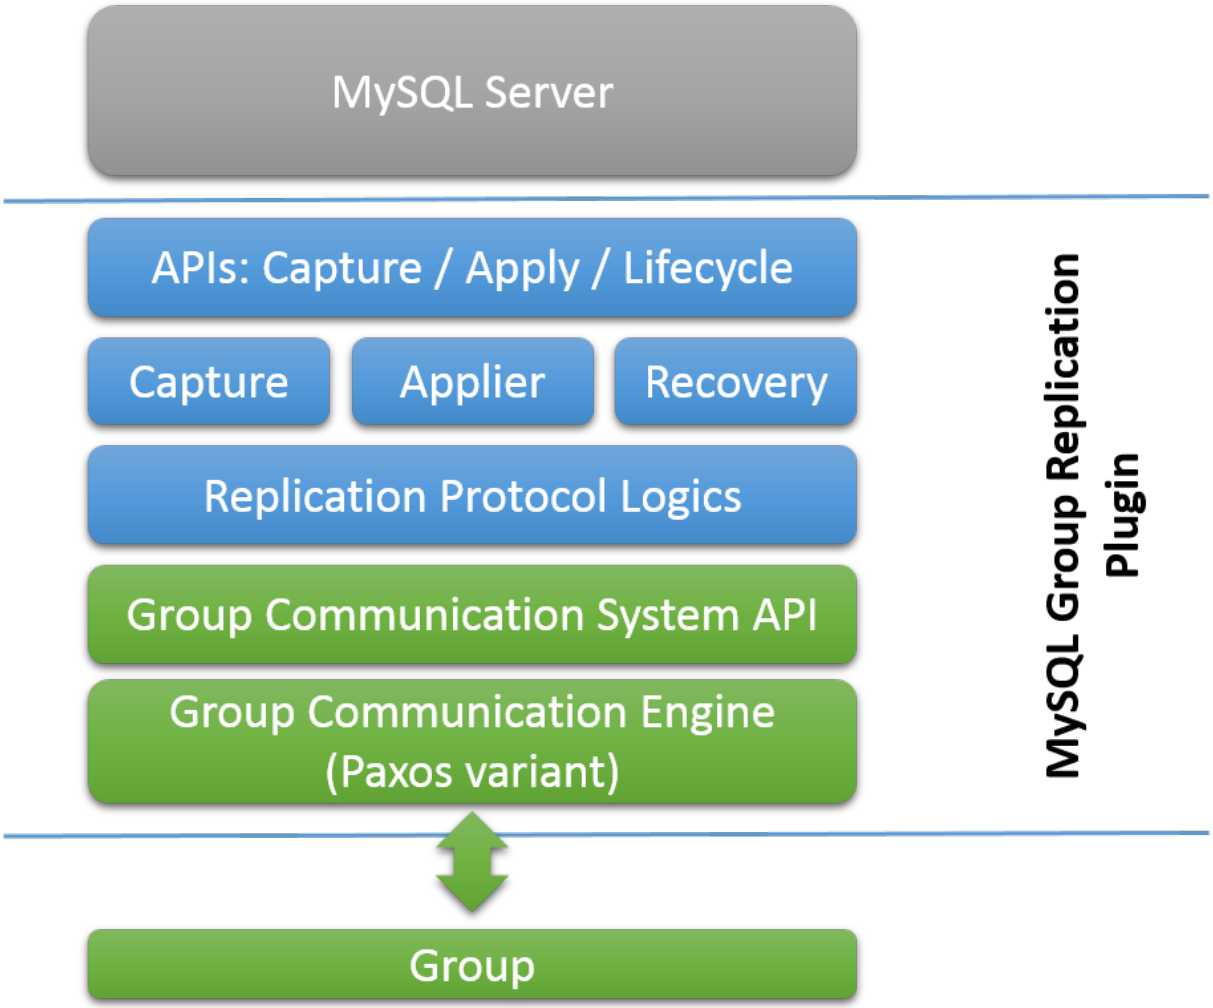
18.11 Group Replication Technical Details

This section provides more technical details about MySQL Group Replication.

18.11.1 Group Replication Plugin Architecture

MySQL Group Replication is a MySQL plugin and it builds on the existing MySQL replication infrastructure, taking advantage of features such as the binary log, row-based logging, and global transaction identifiers. It integrates with current MySQL frameworks, such as the performance schema or plugin and service infrastructures. The following figure presents a block diagram depicting the overall architecture of MySQL Group Replication.

Figure 18.10 Group Replication Plugin Block Diagram



The MySQL Group Replication plugin includes a set of APIs for capture, apply, and lifecycle, which control how the plugin interacts with MySQL Server. There are interfaces to make information flow from the server to the plugin and vice versa. These interfaces isolate the MySQL Server core from the Group Replication plugin, and are mostly hooks placed in the transaction execution pipeline. In

one direction, from server to the plugin, there are notifications for events such as the server starting, the server recovering, the server being ready to accept connections, and the server being about to commit a transaction. In the other direction, the plugin instructs the server to perform actions such as committing or aborting ongoing transactions, or queuing transactions in the relay log.

The next layer of the Group Replication plugin architecture is a set of components that react when a notification is routed to them. The capture component is responsible for keeping track of context related to transactions that are executing. The applier component is responsible for executing remote transactions on the database. The recovery component manages distributed recovery, and is responsible for getting a server that is joining the group up to date by selecting the donor, orchestrating the catch up procedure and reacting to donor failures.

Continuing down the stack, the replication protocol module contains the specific logic of the replication protocol. It handles conflict detection, and receives and propagates transactions to the group.

The final two layers of the Group Replication plugin architecture are the Group Communication System (GCS) API, and an implementation of a Paxos-based group communication engine (XCom). The GCS API is a high level API that abstracts the properties required to build a replicated state machine (see Section 18.1, “Group Replication Background”). It therefore decouples the implementation of the messaging layer from the remaining upper layers of the plugin. The group communication engine handles communications with the members of the replication group.

18.11.2 The Group

In MySQL Group Replication, a set of servers forms a replication group. A group has a name, which takes the form of a UUID. The group is dynamic and servers can leave (either voluntarily or involuntarily) and join it at any time. The group adjusts itself whenever servers join or leave.

If a server joins the group, it automatically brings itself up to date by fetching the missing state from an existing server. This state is transferred by means of Asynchronous MySQL replication. If a server leaves the group, for instance it was taken down for maintenance, the remaining servers notice that it has left and reconfigure the group automatically. The group membership service described at Section 18.1.3.2, “Group Membership” powers all of this.

18.11.3 Data Manipulation Statements

As there are no primary servers (masters) for any particular data set, every server in the group is allowed to execute transactions at any time, even transactions that change state (RW transactions).

Any server may execute a transaction without any *a priori* coordination. But, at commit time, it coordinates with the rest of the servers in the group to reach a decision on the fate of that transaction. This coordination serves two purposes: (i) check whether the transaction should commit or not; (ii) and propagate the changes so that other servers can apply the transaction as well.

As a transaction is sent through an atomic broadcast, either all servers in the group receive the transaction or none do. If they receive it, then they all receive it in the same order with respect to other transactions that were sent before. Conflict detection is carried out by inspecting and comparing write sets of transactions. Thus, they are detected at the row level. Conflict resolution follows the first committer wins rule. If t1 and t2 execute concurrently at different sites, because t2 is ordered before t1, and both changed the same row, then t2 wins the conflict and t1 aborts. In other words, t1 was trying to change data that had been rendered stale by t2.

Note

If two transactions are bound to conflict more often than not, then it is a good practice to start them on the same server. They then have a chance to synchronize on the local lock manager instead of aborting later in the replication protocol.

18.11.4 Data Definition Statements

In a Group Replication topology, care needs to be taken when executing data definition statements, also commonly known as data definition language (DDL).

MySQL 8.0 introduces support for atomic Data Definition Language (DDL) statements, where the complete DDL statement is either committed or rolled back as a single atomic transaction. However, DDL statements, atomic or otherwise, implicitly end any transaction that is active in the current session, as if you had done a `COMMIT` before executing the statement. This means that DDL statements cannot be performed within another transaction, within transaction control statements such as `START TRANSACTION ... COMMIT`, or combined with other statements within the same transaction.

Group Replication is based on an optimistic replication paradigm, where statements are optimistically executed and rolled back later if necessary. Each server executes and commits without securing group agreement first. Therefore, more care needs to be taken when replicating DDL statements in multi-primary mode. If you make schema changes (using DDL) and changes to the data that an object contains (using DML) for the same object, the changes need to be handled through the same server while the schema operation has not yet completed and replicated everywhere. Failure to do so can result in data inconsistency when operations are interrupted or only partially completed. If the group is deployed in single-primary mode this issue does not occur, because all changes are performed through the same server, the primary.

For details on atomic DDL support in MySQL 8.0, and the resulting changes in behavior for the replication of certain statements, see Section 13.1.1, “Atomic Data Definition Statement Support”.

18.11.5 Distributed Recovery

This section describes the process through which a member joining a group catches up with the remaining servers in the group, called distributed recovery.

18.11.5.1 Distributed Recovery Basics

This section is a high level summary. The following sections provide additional detail, by describing the phases of the procedure in more detail.

Group Replication distributed recovery can be summarized as the process through which a server gets missing transactions from the group so that it can then join the group having processed the same set of transactions as the other group members. During distributed recovery, the server joining the group buffers any transactions and membership events that happen while the server joining the group is receiving the transactions required from the group. Once the server joining the group has received all of the group's transactions, it applies the transactions that were buffered during the recovery process. At the end of this process the server then joins the group as an online member.

Phase 1

In the first phase, the server joining the group selects one of the online servers on the group to be the *donor* of the state that it is missing. The donor is responsible for providing the server joining the group all the data it is missing up to the moment it has joined the group. This is achieved by relying on a standard asynchronous replication channel, established between the donor and the server joining the group, see Section 17.2.3, “Replication Channels”. Through this replication channel, the donor's binary logs are replicated until the point that the view change happened when the server joining the group became part of the group. The server joining the group applies the donor's binary logs as it receives them.

While the binary log is being replicated, the server joining the group also caches every transaction that is exchanged within the group. In other words it is listening for transactions that are happening after it joined the group and while it is applying the missing state from the donor. When the first phase ends and the replication channel to the donor is closed, the server joining the group then starts phase two: the catch up.

Phase 2

In this phase, the server joining the group proceeds to the execution of the cached transactions. When the number of transactions queued for execution finally reaches zero, the member is declared online.

Resilience

The recovery procedure withstands donor failures while the server joining the group is fetching binary logs from it. In such cases, whenever a donor fails during phase 1, the server joining the group fails over to a new donor and resumes from that one. When that happens the server joining the group closes the connection to the failed server joining the group explicitly and opens a connection to a new donor. This happens automatically.

18.11.5.2 Recovering From a Point-in-time

To synchronize the server joining the group with the donor up to a specific point in time, the server joining the group and donor make use of the MySQL Global Transaction Identifiers (GTIDs) mechanism. See Section 17.1.3, “Replication with Global Transaction Identifiers”. However, GTIDS only provide a means to realize which transactions the server joining the group is missing, they do not help marking a specific point in time to which the server joining the group must catch up, nor do they help conveying certification information. This is the job of binary log view markers, which mark view changes in the binary log stream, and also contain additional metadata information, provisioning the server joining the group with missing certification related data.

View and View Changes

To explain the concept of view change markers, it is important to understand what a view and a view change are.

A *view* corresponds to a group of members participating actively in the current configuration, in other words at a specific point in time. They are correct and online in the system.

A *view change* occurs when a modification to the group configuration happens, such as a member joining or leaving. Any group membership change results in an independent view change communicated to all members at the same logical point in time.

A *view identifier* uniquely identifies a view. It is generated whenever a view change happens

At the group communication layer, view changes with their associated view ids are then boundaries between the data exchanged before and after a member joins. This concept is implemented through a new binary log event: the"view change log event". The view id thus becomes a marker as well for transactions transmitted before and after changes happen in the group membership.

The view identifier itself is built from two parts: *(i)* one that is randomly generated and *(ii)* a monotonically increasing integer. The first part is generated when the group is created, and remains unchanged while there is at least one member in the group. The second part is incremented every time a view change happens.

The reason for this heterogeneous pair that makes up the view id is the need to unambiguously mark group changes whenever a member joins or leaves but also whenever all members leave the group and no information remains of what view the group was in. In fact, the sole use of monotonic increasing identifiers could lead to the reuse of the same id after full group shutdowns, destroying the uniqueness of the binary log data markers that recovery depends on. To summarize, the first part identifies whenever the group was started from the beginning and the incremental part when the group changed from that point on.

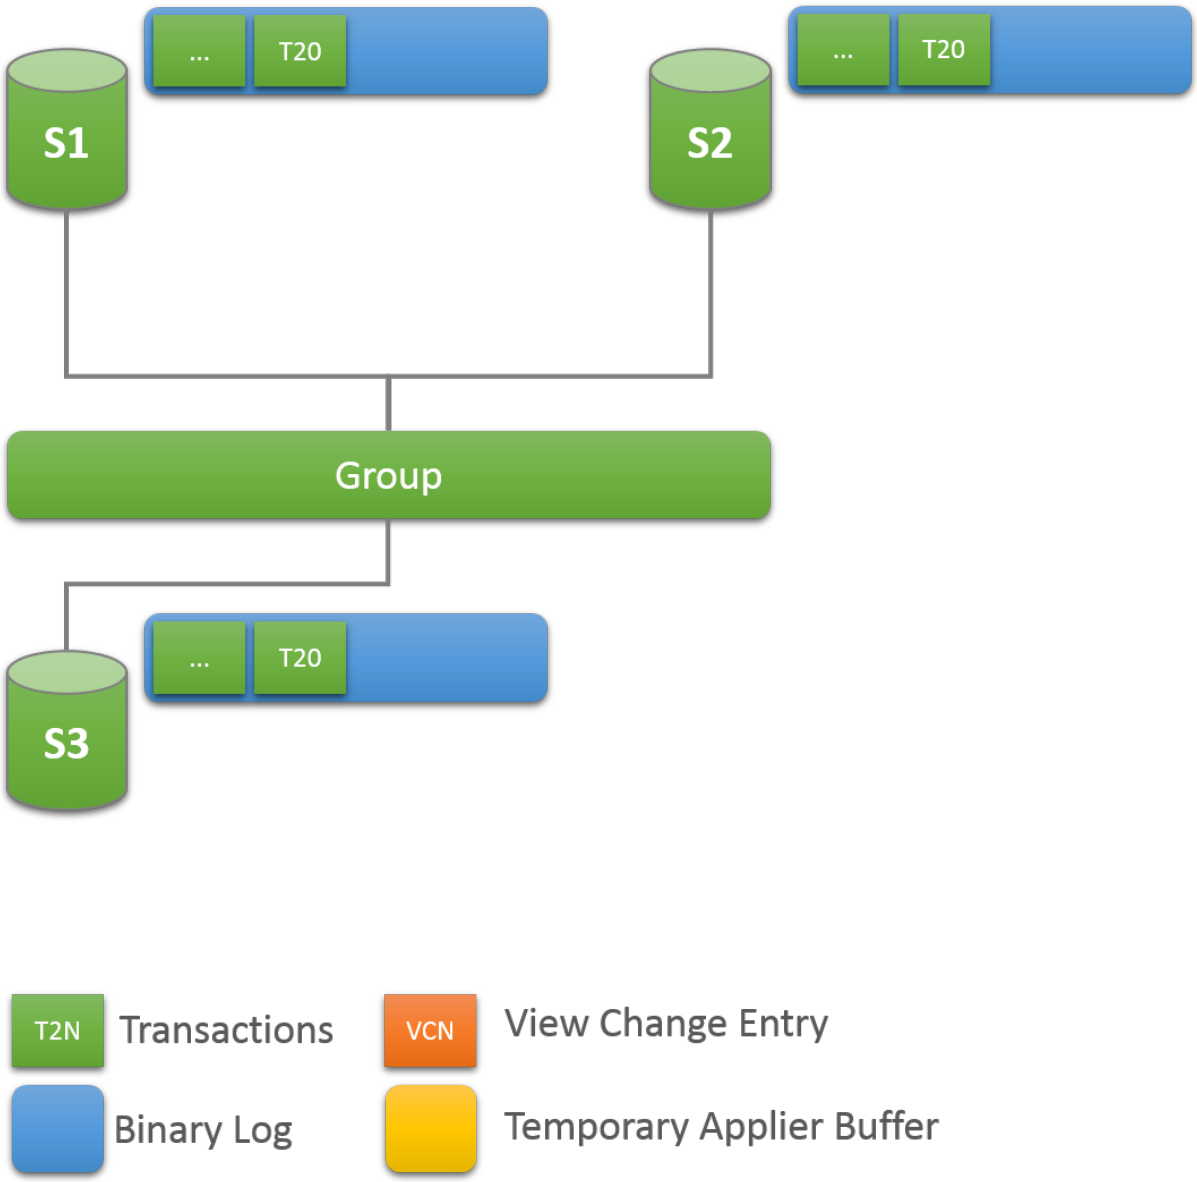
18.11.5.3 View Changes

This section explains the process which controls how the view change identifier is incorporated into a binary log event and written to the log, The following steps are taken:

Begin: Stable Group

All servers are online and processing incoming transactions from the group. Some servers may be a little behind in terms of transactions replicated, but eventually they converge. The group acts as one distributed and replicated database.

Figure 18.11 Stable Group

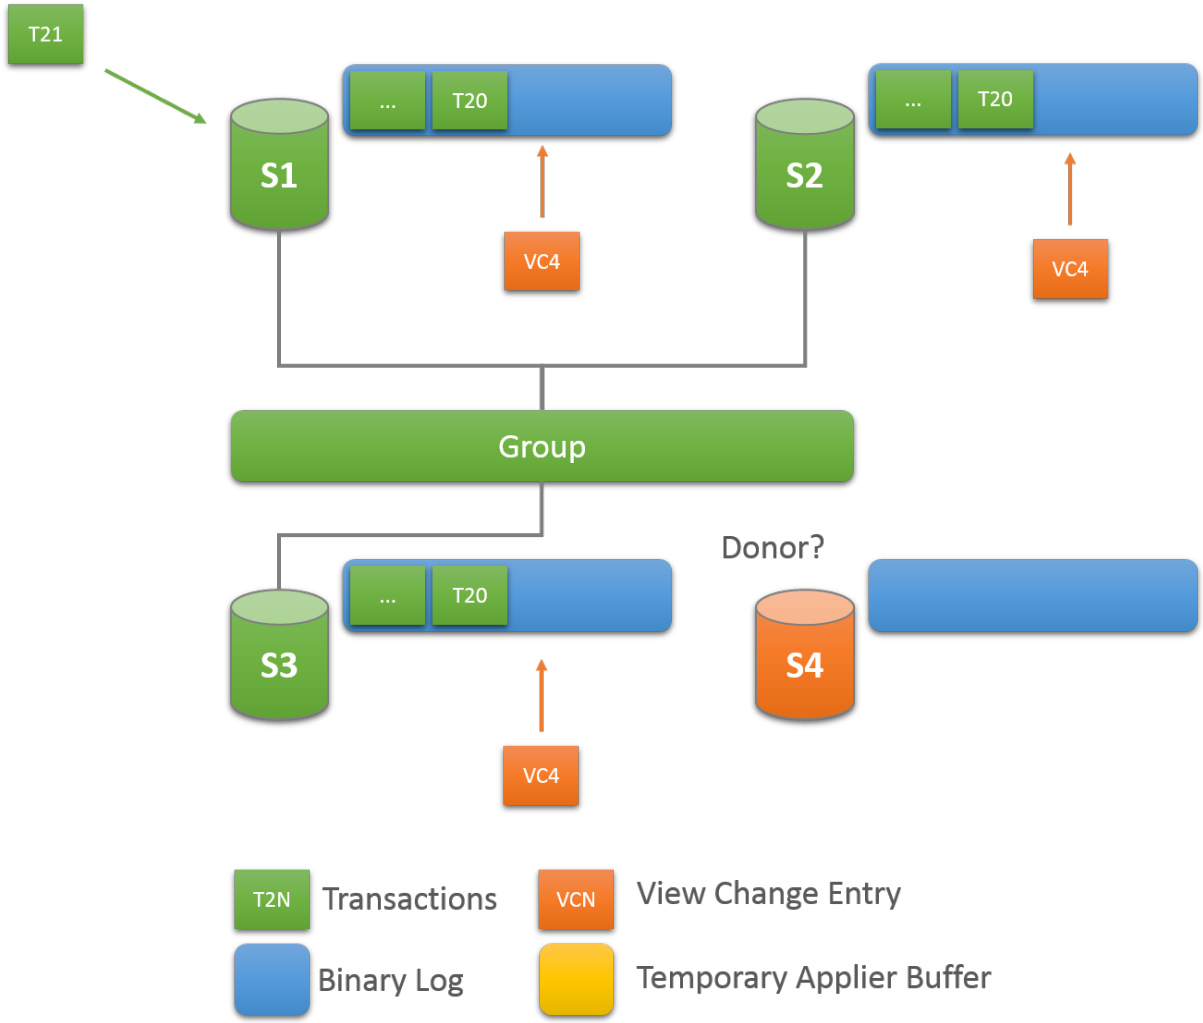


View Change: a Member Joins

Whenever a new member joins the group and therefore a view change is performed, every online server queues a view change log event for execution. This is queued because before the view change, several transactions can be queued on the server to be applied and as such, these belong to the old view. Queuing the view change event after them guarantees a correct marking of when this happened.

Meanwhile, the server joining the group selects the donor from the list of online servers as stated by the membership service through the view abstraction. A member joins on view 4 and the online members write a View change event to the binary log.

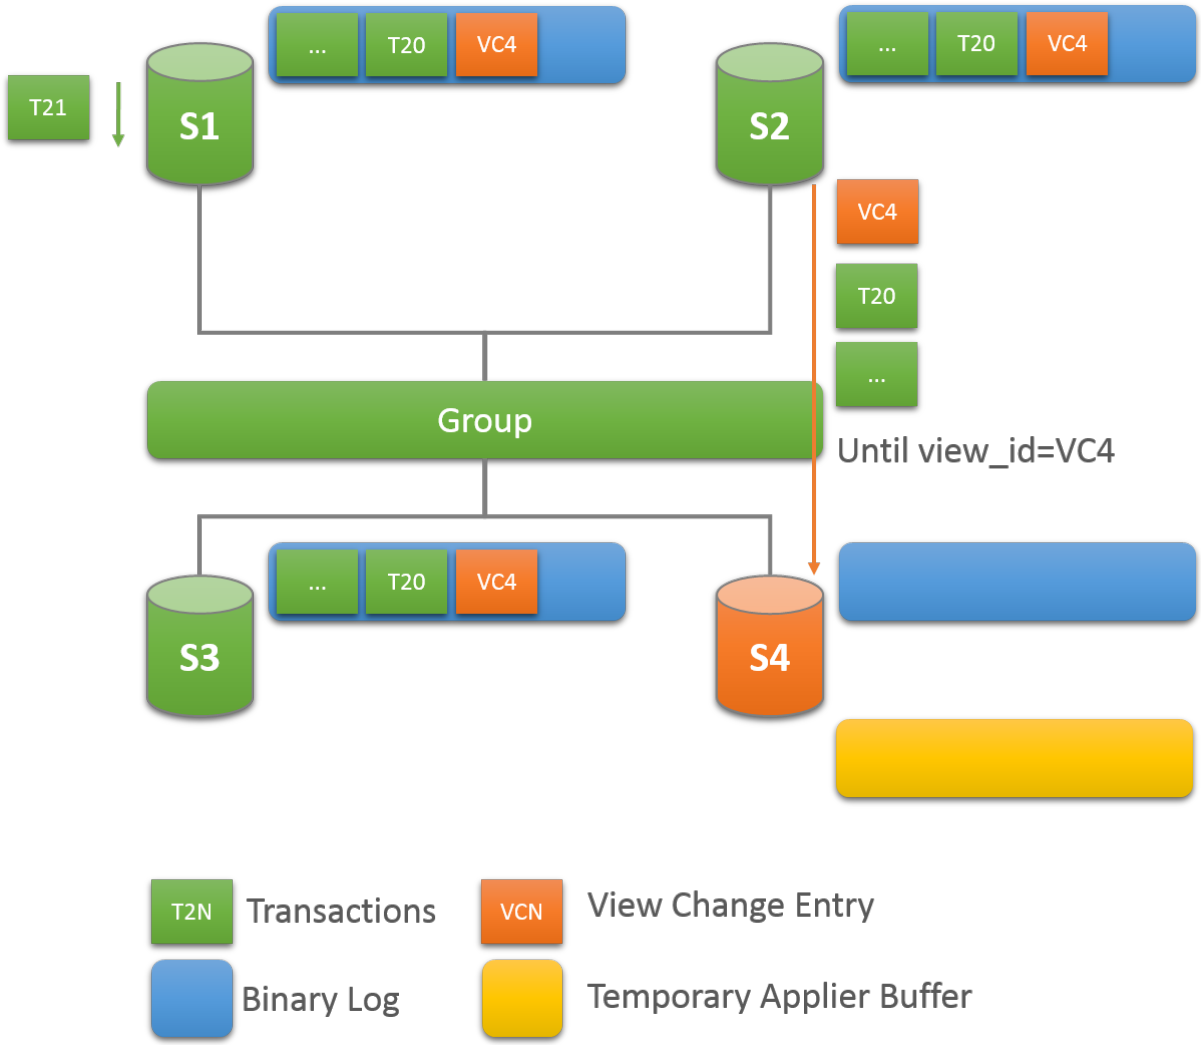
Figure 18.12 A Member Joins



State Transfer: Catching Up

Once the server joining the group has chosen which server in the group is to be the donor, a new asynchronous replication connection is established between the two and the state transfer begins (phase 1). This interaction with the donor continues until the server joining the group's applier thread processes the view change log event that corresponds to the view change triggered when the server joining the group came into the group. In other words, the server joining the group replicates from the donor, until it gets to the marker with the view identifier which matches the view marker it is already in.

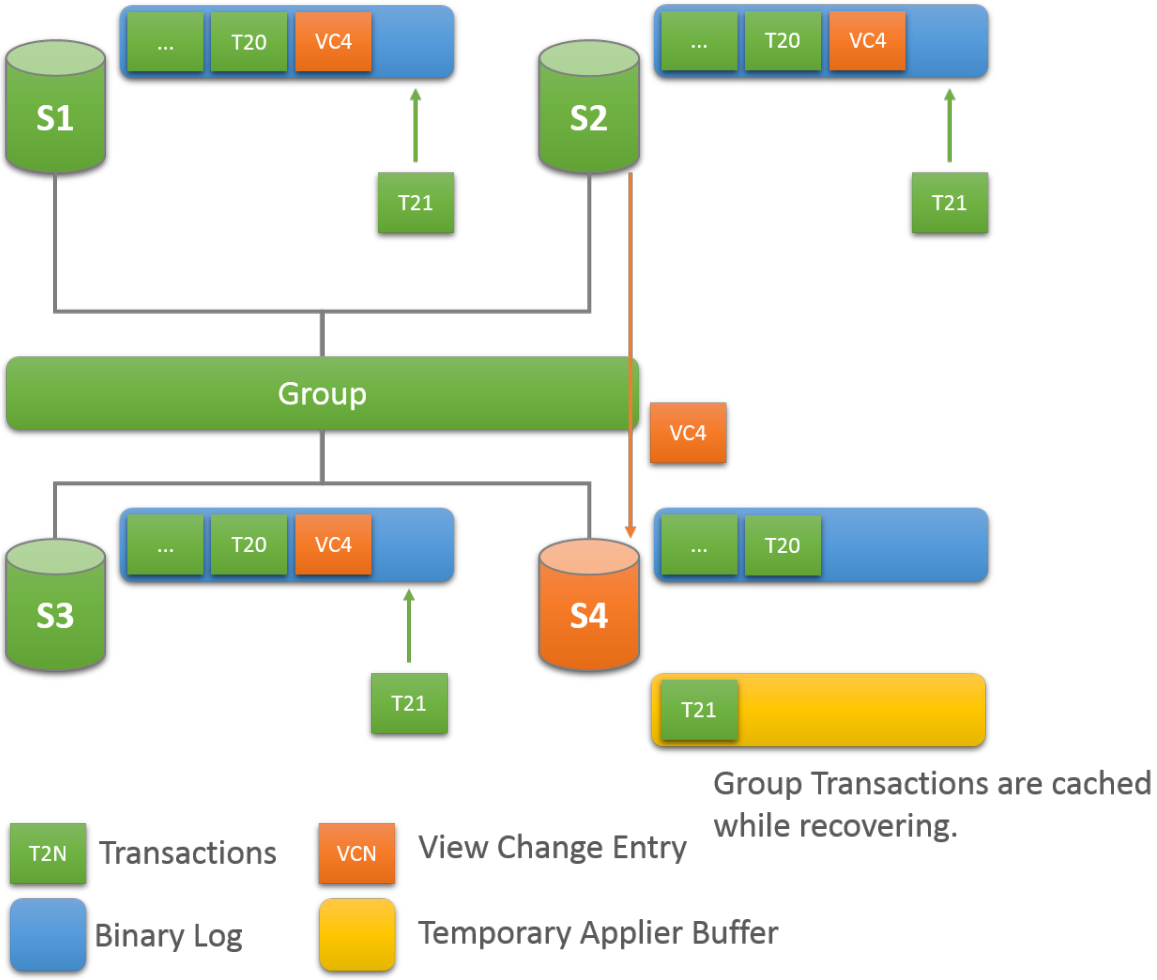
Figure 18.13 State Transfer: Catching Up



As view identifiers are transmitted to all members in the group at the same logical time, the server joining the group knows at which view identifier it should stop replicating. This avoids complex GTID set calculations because the view id clearly marks which data belongs to each group view.

While the server joining the group is replicating from the donor, it is also caching incoming transactions from the group. Eventually, it stops replicating from the donor and switches to applying those that are cached.

Figure 18.14 Queued Transactions



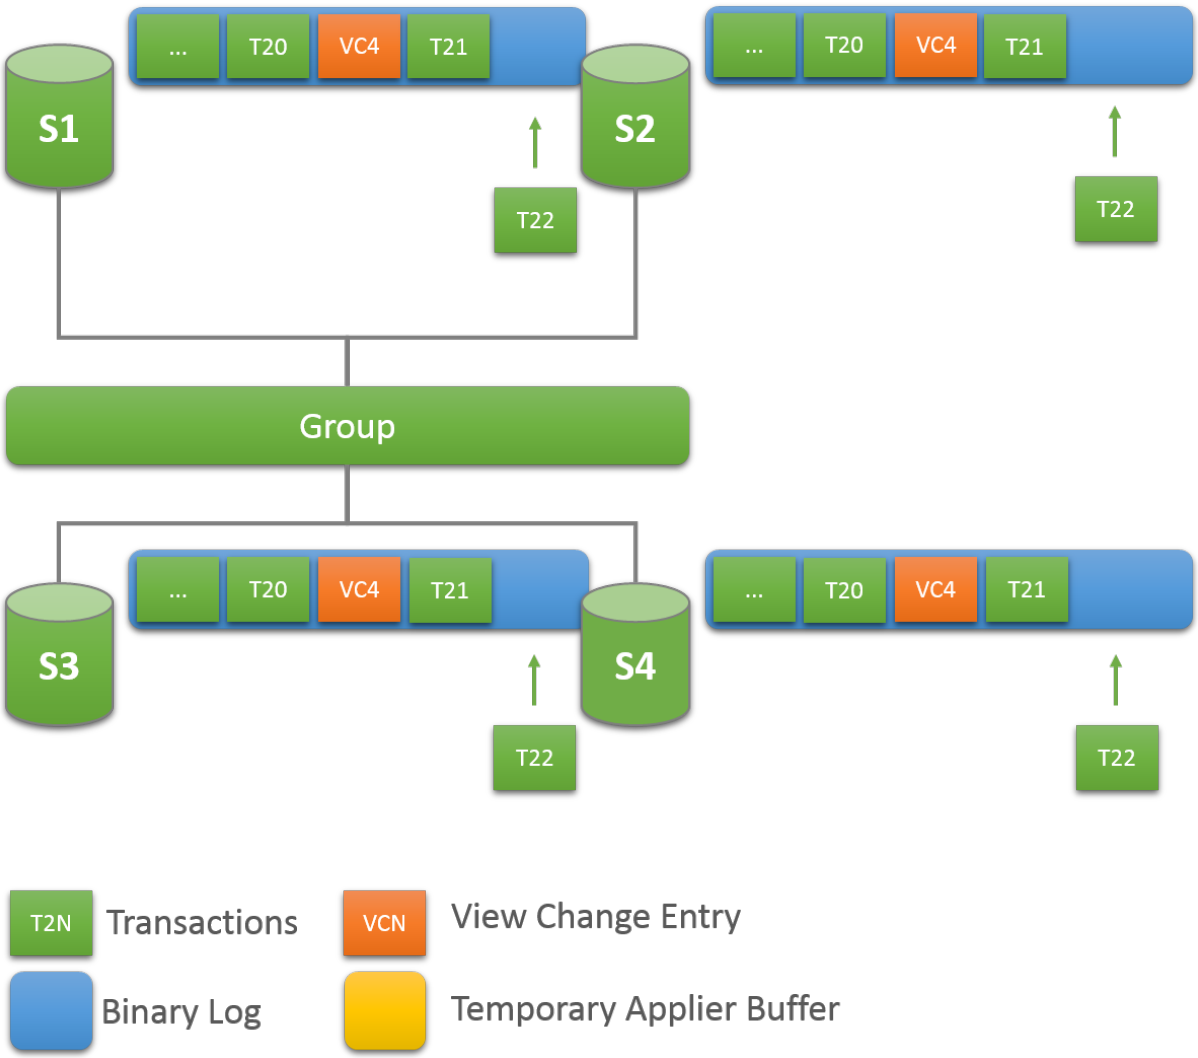
Finish: Caught Up

When the server joining the group recognizes a view change log event with the expected view identifier, the connection to the donor is terminated and it starts applying the cached transactions. An important point to understand is the final recovery procedure. Although it acts as a marker in the binary log, delimiting view changes, the view change log event also plays another role. It conveys the certification information as perceived by all servers when the server joining the group entered the group, in other words the last view change. Without it, the server joining the group would not have the necessary information to be able to certify (detect conflicts) subsequent transactions.

The duration of the catch up (phase 2) is not deterministic, because it depends on the workload and the rate of incoming transactions to the group. This process is completely online and the server joining the group does not block any other server in the group while it is catching up. Therefore the number of transactions the server joining the group is behind when it moves to phase 2 can, for this reason, vary and thus increase or decrease according to the workload.

When the server joining the group reaches zero queued transactions and its stored data is equal to the other members, its public state changes to online.

Figure 18.15 Instance Online



18.11.5.4 Usage Advice and Limitations of Distributed Recovery

Distributed recovery does have some limitations. It is based on classic asynchronous replication and as such it may be slow if the server joining the group is not provisioned at all or is provisioned with a very old backup image. This means that if the data to transfer is too big at phase 1, the server may take a very long time to recover. As such, the recommendation is that before adding a server to the group, one should provision it with a fairly recent snapshot of a server already in the group. This minimizes the length of phase 1 and reduces the impact on the donor server, since it has to save and transfer less binary logs.

Warning

It is recommended that a server is provisioned before it is added to a group. That way, one minimizes the time spent on the recovery step.

18.11.6 Observability

There is a lot of automation built into the Group Replication plugin. Nonetheless, you might sometimes need to understand what is happening behind the scenes. This is where the instrumentation of Group Replication and Performance Schema becomes important. The entire state of the system (including the view, conflict statistics and service states) can be queried through performance_schema tables. The distributed nature of the replication protocol and the fact that server instances agree and thus

synchronize on transactions and metadata makes it simpler to inspect the state of the group. For example, you can connect to a single server in the group and obtain both local and global information by issuing select statements on the Group Replication related Performance Schema tables. For more information, see Section 18.3, “Monitoring Group Replication”.

Chapter 19 MySQL Shell

MySQL Shell is an advanced client and code editor for MySQL Server. In addition to the provided SQL functionality, similar to `mysql`, MySQL Shell provides scripting capabilities for JavaScript and Python and includes APIs for working with MySQL.

The following discussion briefly describes MySQL Shell's capabilities. For more information, see the MySQL Shell manual, available at https://dev.mysql.com/doc/mysql-shell/en/.

MySQL Shell includes the following APIs implemented in JavaScript and Python which you can use to develop code that interacts with MySQL.

- The X DevAPI enables you to work with both relational and document data when MySQL Shell is connected to a MySQL server using the X Protocol. For more information, see Chapter 20, *Using MySQL as a Document Store*. For documentation on the concepts and usage of X DevAPI, see X DevAPI User Guide.
- The AdminAPI enables you to work with InnoDB cluster, which provides an integrated solution for high availability and scalability using InnoDB based MySQL databases, without requiring advanced MySQL expertise. See Chapter 21, *InnoDB Cluster*.

MySQL Shell is available in two editions, the Community Edition and the Commercial Edition. The Community Edition is available free of charge. The Commercial Edition provides additional Enterprise features at low cost.

Chapter 20 Using MySQL as a Document Store

Table of Contents

20.1 Interfaces to a MySQL Document Store 3188
20.2 Document Store Concepts 3188

20.3.1 Import Database Sample 3189
20.3.2 MySQL Shell 3190
20.3.3 Documents and Collections 3192
20.3.4 Relational Tables 3202
20.3.5 Documents in Tables 3208
20.4 Python Quick-Start Guide: MySQL Shell for Document Store 3209
20.4.1 Import Database Sample 3209
20.4.2 MySQL Shell 3210
20.4.3 Documents and Collections 3212
20.4.4 Relational Tables 3222
20.4.5 Documents in Tables 3228
20.5 X Plugin 3229
20.5.1 Checking X Plugin Installation 3229
20.5.2 Disabling X Plugin 3229
20.5.3 Using Secure Connections with X Plugin 3229
20.5.4 Using X Plugin with the Caching SHA-2 Authentication Plugin 3230
20.5.5 X Plugin Options and Variables 3230
20.5.6 Monitoring X Plugin 3241

This chapter introduces an alternative way of working with MySQL as a document store, sometimes referred to as “using NoSQL”. If your intention is to use MySQL in a traditional (SQL) way, this chapter is probably not relevant to you.

Traditionally, relational databases such as MySQL have usually required a schema to be defined before documents can be stored. The features described in this section enable you to use MySQL as a document store, which is a schema-less, and therefore schema-flexible, storage system for documents. For example, when you create documents describing products, you do not need to know and define all possible attributes of any products before storing and operating with the documents. This differs from working with a relational database and storing products in a table, when all columns of the table must be known and defined before adding any products to the database. The features described in this chapter enable you to choose how you configure MySQL, using only the document store model, or combining the flexibility of the document store model with the power of the relational model.

To use MySQL as a document store, you use the following server features:

- X Plugin enables MySQL Server to communicate with clients using X Protocol, which is a prerequisite for using MySQL as a document store. X Plugin is enabled by default in MySQL Server as of MySQL 8.0. For instructions to verify X Plugin installation and to configure and monitor X Plugin, see Section 20.5, “X Plugin”.

- X Protocol supports both CRUD and SQL operations, authentication via SASL, allows streaming (pipelining) of commands and is extensible on the protocol and the message layer. Clients compatible with X Protocol include MySQL Shell and MySQL 8.0 Connectors.

- Clients that communicate with a MySQL Server using X Protocol can use X DevAPI to develop applications. X DevAPI offers a modern programming interface with a simple yet powerful design which provides support for established industry standard concepts. This chapter explains how to get started using either the JavaScript or Python implementation of X DevAPI in MySQL Shell as a client. See X DevAPI User Guide for in-depth tutorials on using X DevAPI.

20.1 Interfaces to a MySQL Document Store

To work with MySQL as a document store, you use dedicated components and a choice of clients that support communicating with the MySQL server to develop document based applications.

- The following MySQL products support X Protocol and enable you to use X DevAPI in your chosen language to develop applications that communicate with a MySQL Server functioning as a document store:
  - MySQL Shell (which provides implementations of X DevAPI in JavaScript and Python)
  - Connector/C++
  - Connector/J
  - Connector/Node.js
  - Connector/NET
  - Connector/Python
- MySQL Shell is an interactive interface to MySQL supporting JavaScript, Python, or SQL modes. You can use MySQL Shell to prototype applications, execute queries and update data. Installing MySQL Shell has instructions to download and install MySQL Shell.
- The quick-start guides (tutorials) in this chapter help you to get started using MySQL Shell with MySQL as a document store.

  The quick-start guide for JavaScript is here: Section 20.3, “JavaScript Quick-Start Guide: MySQL Shell for Document Store”.

  The quick-start guide for Python is here: Section 20.4, “Python Quick-Start Guide: MySQL Shell for Document Store”.
- The *MySQL Shell User Guide* at MySQL Shell 8.0 (part of MySQL 8.0) provides detailed information about configuring and using MySQL Shell.

20.2 Document Store Concepts

This section explains the concepts introduced as part of using MySQL as a document store.

JSON Document

A JSON document is a data structure composed of key-value pairs and is the fundamental structure for using MySQL as document store. For example, the world_x schema (installed later in this chapter) contains this document:

```
{
    "GNP": .6,
    "IndepYear": 1967,
    "Name": "Sealand",
    "_id": "SEA",
    "demographics": {
        "LifeExpectancy": 79,
        "Population": 27
    },
    "geography": {
        "Continent": "Europe",
        "Region": "British Islands",
        "SurfaceArea": 193
    },
    "government": {
```

```
        "GovernmentForm": "Monarchy",
        "HeadOfState": "Michael Bates"
    }
}
```

This document shows that the values of keys can be simple data types, such as integers or strings, but can also contain other documents, arrays, and lists of documents. For example, the `geography` key's value consists of multiple key-value pairs. A JSON document is represented internally using the MySQL binary JSON object, through the `JSON` MySQL datatype.

The most important differences between a document and the tables known from traditional relational databases are that the structure of a document does not have to be defined in advance, and a collection can contain multiple documents with different structures. Relational tables on the other hand require that their structure be defined, and all rows in the table must contain the same columns.

Collection

A collection is a container that is used to store JSON documents in a MySQL database. Applications usually run operations against a collection of documents, for example to find a specific document.

CRUD Operations

The four basic operations that can be issued against a collection are Create, Read, Update and Delete (CRUD). In terms of MySQL this means:

- Create a new document (insertion or addition)
- Read one or more documents (queries)
- Update one or more documents
- Delete one or more documents

20.3 JavaScript Quick-Start Guide: MySQL Shell for Document Store

This quick-start guide provides instructions to begin prototyping document store applications interactively with MySQL Shell. The guide includes the following topics:

- Introduction to MySQL functionality, MySQL Shell, and the `world_x` database sample.
- Operations to manage collections and documents.
- Operations to manage relational tables.
- Operations that apply to documents within tables.

Related Information

- MySQL Shell 8.0 (part of MySQL 8.0) provides more in-depth information about MySQL Shell.
- X DevAPI User Guide provides more examples of using X DevAPI.
- A Python quick-start guide is also available.

20.3.1 Import Database Sample

The `world_x` database sample contains one JSON collection and a set of three relational tables:

- Collection

    - countryinfo: Information about countries in the world.
- Tables
    - country: Minimal information about countries of the world.
    - city: Information about some of the cities in those countries.
    - countrylanguage: Languages spoken in each country.

Requirements

To follow this quick-start guide you need a MySQL server with X Plugin installed, the default in 8.0, and MySQL Shell to use as the client. See Installing MySQL Shell. Start MySQL before you load the example `world_x` database for this guide.

Download and Import world_x Database

To prepare the `world_x` database sample, follow these steps:

1. Download world_x-db.zip.
2. Extract the installation archive to a temporary location such as `/tmp/`. Unpacking the archive results in a single file named `world_x.sql`.
3. Import the `world_x.sql` file to your database. You can either:
    - Start MySQL Shell in SQL mode and import the file by issuing:

      ```
      mysqlsh -u root --sql --file /tmp/world_x-db/world_x.sql
      Enter password: ****
      ```

    - Set MySQL Shell to SQL mode while it is running and source the schema file while MySQL Shell is running by issuing:

      ```
      \source /tmp/world_x-db/world_x.sql
      Switching to SQL mode... Commands end with ;
      \source /tmp/world_x-db/world_x.sql
      ```

    Replace `/tmp/` with the path to the `world_x.sql` file on your system. Enter your password when prompted. A non-root account can be used as long as the account has privileges to create new databases.

Related Information

- MySQL Shell Sessions explains session types.
- See Chapter 2, *Installing and Upgrading MySQL* for general installation assistance.

20.3.2 MySQL Shell

MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. JavaScript is the default processing mode. In most cases, you need an account to connect to the MySQL server instance.

Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. By default, MySQL Shell connects using X Protocol. You need to know the address of the MySQL server instance you plan to connect to.

If MySQL Shell is not already running, open a terminal window and issue:

```
mysqlsh name@host/world_x
```

Alternatively, if MySQL Shell is already running use the `\connect` command by issuing:

```
\connect name@host/world_x
```

You need to specify the address of your MySQL server instance which you want to connect MySQL Shell to. For example in the previous example:

- *`name`* represents the user name of your MySQL account.
- MySQL Shell prompts you for your password.
- The default schema for this session is the `world_x` database. For instructions on setting up the `world_x` database sample, see Section 20.3.1, “Import Database Sample”.

Once MySQL Shell opens, the `mysql-js>` prompt indicates that the active language for this session is JavaScript.

```
mysql-js>
```

When you run `mysqlsh` without the host argument, MySQL Shell attempts to connect to the server instance running on the localhost interface on port 33060. For more information, see MySQL Shell Connections.

MySQL Shell supports input-line editing as follows:

- **left-arrow** and **right-arrow** keys move horizontally within the current input line.
- **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines.
- **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position.
- **Enter** sends the current input line to the server.

Get Help for MySQL Shell

Type `mysqlsh --help` at the prompt of your command interpreter for a list of command-line options.

```
mysqlsh --help
```

Type `\help` at the MySQL Shell prompt for a list of available commands and their descriptions.

```
mysql-js> \help
```

Type `\help` followed by a command name for detailed help about an individual MySQL Shell command. For example, to view help on the `\connect` command, type:

```
mysql-js> \help \connect
```

Quit MySQL Shell

To quit MySQL Shell, type the following command:

```
```

```
mysql-js> \quit
```

Related Information

- See Interactive Code Execution for an explanation of how interactive code execution works in MySQL Shell.
- See Getting Started with MySQL Shell to learn about session and connection alternatives.
- See Section 4.2.3, “Connecting Using a URI or Key-Value Pairs” to learn about specifying the location of a MySQL server.

20.3.3 Documents and Collections

In MySQL, collections contain JSON documents that you can add, find, update, and remove. Collections are containers within a schema that you can create, list, and drop.

The examples in this section use the countryinfo collection in the `world_x` database. For instructions on setting up the `world_x` database sample, see Section 20.3.1, “Import Database Sample”.

Documents

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for JavaScript:

```
{field1: "value", field2 : 10, "field 3": null}
```

An array of documents consists of a set of documents separated by commas and enclosed within `[` and `]` characters.

- Simple array of documents for JavaScript:

```
[{Name: "Aruba", _id: "ABW"}, {Name: "Angola", _id: "AGO"}]
```

MySQL supports the following JavaScript value types in JSON documents:

- numbers (integer and floating point)
- strings
- boolean (False and True)
- null
- arrays of more JSON values
- nested (or embedded) objects of more JSON values

Collections

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.

The term schema is equivalent to a database, which means a group of database objects (as opposed to relational schema used to enforce structure and constraints over data). A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

- Basic objects include:

Object form	Description
`db`	`db` is a global variable assigned to the current active schema. When you want to run operations against the schema, for example to retrieve a collection, you use methods available for the `db` variable.
`db.getCollections()`	db.getCollections() holds a list of collections in the schema. Use the list to get references to collection objects, iterate over them, and so on.

- Basic operations scoped by collections include:

Operation form	Description
`db.`*`name`*`.add()`	The add() method inserts one document or a list of documents into the named collection.
`db.`*`name`*`.find()`	The find() method returns some or all documents in the named collection.
`db.`*`name`*`.modify()`	The modify() method updates documents in the named collection.
`db.`*`name`*`.remove()`	The remove() method deletes one document or a list of documents from the named collection.

Related Information

- See Working with Collections for a general overview.
- CRUD EBNF Definitions provides a complete list of operations.

20.3.3.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.

Confirm the Schema

To show the value that is assigned to the schema variable, issue:

```
mysql-js> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable by issuing:

```
mysql-js> \use world_x
```

Create a Collection

To create a new collection in an existing schema, use the `db` object's `createCollection()` method. The following example creates a collection called `flags` in the `world_x` database.

```
mysql-js> db.createCollection("flags")
```

The method returns a collection object.

```
<Collection:flags>
```

List Collections

To display all collections in the `world_x` database, use the `db` object's `getCollections()` method. Collections returned by the server you are currently connected to appear between brackets.

```
mysql-js> db.getCollections()
[
    <Collection:countryinfo>,
    <Collection:flags>
]
```

Drop a Collection

To drop an existing collection from a database, use the `db` object's `dropCollection()` method. For example, to drop the flags collection from the `world_x` database, type:

```
mysql-js> db.dropCollection("flags")
```

The `dropCollection()` method is also used in MySQL Shell to drop a relational table from a database.

Related Information

- See Collection Objects for more examples.

20.3.3.2 Add Documents

Use the `add()` method to insert one document or a list of documents into an existing collection using MySQL Shell. All examples in this section use the countryinfo collection, which is provided in the `world_x` schema.

Add a Document

Insert the following document into the countryinfo collection. As this is multi-line content, press **Enter** twice to insert the document.

```
mysql-js> db.countryinfo.add(
 {
    GNP: .6,
    IndepYear: 1967,
    Name: "Sealand",
    demographics: {
        LifeExpectancy: 79,
        Population: 27
    },
    geography: {
        Continent: "Europe",
        Region: "British Islands",
        SurfaceArea: 193
    },
    government: {
        GovernmentForm: "Monarchy",
        HeadOfState: "Michael Bates"
    }
  }
)
```

The method returns the status of the operation.

Each document requires an identifier field called `_id`. The value of the `_id` field must be unique among all documents in the same collection. In MySQL 8.0.11 and higher, document IDs are generated by the server, not the client, so MySQL Shell does not automatically set an `_id` value. A MySQL server at 8.0.11 or higher sets an `_id` value if the document does not contain the `_id` field. A MySQL server

at an earlier 8.0 release or at 5.7 does not set an `_id` value in this situation, so you must specify it explicitly. If you do not, MySQL Shell returns error 5115 `Document is missing a required field`.

Related Information

- See CollectionAddFunction for the full syntax definition.
- See Understanding Document IDs.

20.3.3.3 Find Documents

You can use the `find()` method to query for and return documents from a collection in a database. MySQL Shell provides additional methods to use with the `find()` method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: `OR` (`||`), `AND` (`&&`), `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Find All Documents in a Collection

To return all documents in a collection, use the `find()` method without specifying search conditions. For example, the following operation returns all documents in the countryinfo collection.

```
mysql-js> db.countryinfo.find()
[
     {
          "GNP": 828,
          "IndepYear": null,
          "Name": "Aruba",
          "_id": "ABW",
          "demographics": {
              "LifeExpectancy": 78.4000015258789,
              "Population": 103000
          },
          "geography": {
              "Continent": "North America",
              "Region": "Caribbean",
              "SurfaceArea": 193
          },
          "government": {
              "GovernmentForm": "Nonmetropolitan Territory of The Netherlands",
              "HeadOfState": "Beatrix"
          }
          ...
      }
 ]
240 documents in set (0.00 sec)
```

The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

You can include search conditions with the `find()` method. The syntax for expressions that form a search condition is the same as that of traditional MySQL Chapter 12, *Functions and Operators*. You must enclose all expressions in quotes.

All examples in this section use the countryinfo collection in the `world_x` database. For the sake of brevity, some of the examples do not display output.

A simple search condition could consist of the `Name` field and a value we know is in a document. The following example returns a single document:

```
mysql-js> db.countryinfo.find("Name = 'Australia'")
[
    {
        "GNP": 351182,
        "IndepYear": 1901,
        "Name": "Australia",
        "_id": "AUS",
        "demographics": {
            "LifeExpectancy": 79.80000305175781,
            "Population": 18886000
        },
        "geography": {
            "Continent": "Oceania",
            "Region": "Australia and New Zealand",
            "SurfaceArea": 7741220
        },
        "government": {
            "GovernmentForm": "Constitutional Monarchy, Federation",
            "HeadOfState": "Elisabeth II"
        }
    }
]
```

The following example searches for all countries that have a GNP higher than $500 billion. The countryinfo collection measures GNP in units of million.

```
mysql-js> db.countryinfo.find("GNP > 500000")
...[output removed]
10 documents in set (0.00 sec)
```

The Population field in the following query is embedded within the demographics object. To access the embedded field, use a period between demographics and Population to identify the relationship. Document and field names are case-sensitive.

```
mysql-js> db.countryinfo.find("GNP > 500000 and demographics.Population < 100000000")
...[output removed]
6 documents in set (0.00 sec)
```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than $30000. Search conditions can include arithmetic operators and most MySQL functions.

Note

Seven documents in the countryinfo collection have a population value of zero. Warning messages appear at the end of the output.

```
mysql-js> db.countryinfo.find("GNP*1000000/demographics.Population > 30000")
...[output removed]
9 documents in set, 7 warnings (0.00 sec)
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as *country*. Then use the `bind(placeholder, value)` method as follows:

```
mysql-js> db.countryinfo.find("Name = :country").bind("country", "Italy")
[
    {
        "GNP": 1161755,
        "IndepYear": 1861,
        "Name": "Italy",
        "_id": "ITA",
        "demographics": {
            "LifeExpectancy": 79,
            "Population": 57680000
        },
        "geography": {
            "Continent": "Europe",
            "Region": "Southern Europe",
            "SurfaceArea": 301316
        },
        "government": {
            "GovernmentForm": "Republic",
            "HeadOfState": "Carlo Azeglio Ciampi"
        }
    }
]
1 document in set (0.01 sec)
```

Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

You can use placeholders and the `bind()` method to create saved searches which you can then call with different values. For example to create a saved search for a country:

```
mysql-js> var myFind = db.countryinfo.find("Name = :country")
mysql-js> myFind.bind('country', 'France')
[
    {
        "GNP": 1424285,
        "IndepYear": 843,
        "Name": "France",
        "_id": "FRA",
        "demographics": {
            "LifeExpectancy": 78.80000305175781,
            "Population": 59225700
        },
        "geography": {
            "Continent": "Europe",
            "Region": "Western Europe",
            "SurfaceArea": 551500
        },
        "government": {
            "GovernmentForm": "Republic",
            "HeadOfState": "Jacques Chirac"
        }
    }
]
1 document in set (0.0028 sec)

mysql-js> myFind.bind('country', 'Germany')
[
    {
        "GNP": 2133367,
        "IndepYear": 1955,
        "Name": "Germany",
```

```
        "_id": "DEU",
        "demographics": {
            "LifeExpectancy": 77.4000015258789,
            "Population": 82164700
        },
        "geography": {
            "Continent": "Europe",
            "Region": "Western Europe",
            "SurfaceArea": 357022
        },
        "government": {
            "GovernmentForm": "Federal Republic",
            "HeadOfState": "Johannes Rau"
        }
    }
]
1 document in set (0.0026 sec)
```

Project Results

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the countryinfo collection matching the search conditions.

Use the `fields()` method to pass the list of fields to return.

```
mysql-js> db.countryinfo.find("GNP > 5000000").fields(["GNP", "Name"])
[
    {
        "GNP": 8510700,
        "Name": "United States"
    }
]
1 document in set (0.00 sec)
```

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new field values—with an expression that describes the document to return. For example, alter the names of the fields with the following expression to return only two documents.

```
mysql-js> db.countryinfo.find().
fields(mysqlx.expr('{"Name": upper(Name), "GNPPerCapita": GNP*1000000/demographics.Population}')).
limit(2)
[
    {
        "GNPPerCapita": 8038.834951456311,
        "Name": "ARUBA"
    },
    {
        "GNPPerCapita": 263.0281690140845,
        "Name": "AFGHANISTAN"
    }
]
2 documents in set (0.00 sec)
```

Limit, Sort, and Skip Results

You can apply the `limit()`, `sort()`, and `skip()` methods to manage the number and order of documents returned by the `find()` method.

To specify the number of documents included in a result set, append the `limit()` method with a value to the `find()` method. The following query returns the first five documents in the countryinfo collection.

```
mysql-js> db.countryinfo.find().limit(5)
... [output removed]
```

```
5 documents in set (0.00 sec)
```

To specify an order for the results, append the `sort()` method to the `find()` method. Pass to the `sort()` method a list of one or more fields to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all documents by the IndepYear field and then returns the first eight documents in descending order.

```
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8)
... [output removed]
8 documents in set (0.00 sec)
```

By default, the `limit()` method starts from the first document in the collection. You can use the `skip()` method to change the starting document. For example, to ignore the first document and return the next eight documents matching the condition, pass to the `skip()` method a value of 1.

```
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)
```

Related Information

- The MySQL Reference Manual provides detailed documentation on functions and operators.
- See CollectionFindFunction for the full syntax definition.

20.3.3.4 Modify Documents

You can use the `modify()` method to update one or more documents in a collection. The X DevAPI provides additional methods for use with the `modify()` method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.
- Bind, limit, and sort the documents to be modified.

Set and Unset Fields

The `modify()` method works by filtering a collection to include only the documents to be modified and then applying the operations that you specify to those documents.

In the following example, the `modify()` method uses the search condition to identify the document to change and then the `set()` method replaces two values within the nested demographics object.

```
mysql-js> db.countryinfo.modify("_id = 'SEA'").\
set("demographics", {LifeExpectancy: 78, Population: 28})
Query OK, 1 item affected (0.04 sec)
```

After you modify a document, use the `find()` method to verify the change.

To remove content from a document, use the `modify()` and `unset()` methods. For example, the following query removes the GNP from a document that matches the search condition.

```
mysql-js> db.countryinfo.modify("Name = 'Sealand'").unset("GNP")
Query OK, 1 item affected (0.01 sec)
```

Use the `find()` method to verify the change.

```
mysql-js> db.countryinfo.find("Name = 'Sealand'")
```

```
[
    {
        "IndepYear": 1967,
        "Name": "Sealand",
        "_id": "SEA",
        "demographics": {
            "LifeExpectancy": 78,
            "Population": 28
        },
        "geography": {
            "Continent": "Europe",
            "Region": "British Islands",
            "SurfaceArea": 193
        },
        "government": {
            "GovernmentForm": "Monarchy",
            "HeadOfState": "Michael Bates"
        }
    }
]
1 document in set (0.00 sec)
```

Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the `arrayAppend()`, `arrayInsert()`, or `arrayDelete()` methods. The following examples modify the countryinfo collection to enable tracking of international airports.

The first example uses the `modify()` and `set()` methods to create a new Airports field in all documents.

Caution

Use care when you modify documents without specifying a search condition. This action will modify all documents in the collection.

```
mysql-js> db.countryinfo.modify("true").set("Airports", [])
Query OK, 240 items affected (0.07 sec)
```

With the Airports field added, the next example uses the `arrayAppend()` method to add a new airport to one of the documents. *$.Airports* in the following example represents the Airports field of the current document.

```
mysql-js> db.countryinfo.modify("Name = 'France'").arrayAppend("$.Airports", "ORY")
Query OK, 1 item affected (0.02 sec)
```

Use **`db.countryinfo.find("Name = 'France'")`** to see the change.

To insert an element at a different position in the array, use the `arrayInsert()` method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```
mysql-js> db.countryinfo.modify("Name = 'France'").arrayInsert("$.Airports[0]", "CDG")
Query OK, 1 item affected (0.04 sec)
```

To delete an element from the array, you must pass to the `arrayDelete()` method the index of the element to be deleted.

```
mysql-js> db.countryinfo.modify("Name = 'France'").arrayDelete("$.Airports[1]")
Query OK, 1 item affected (0.03 sec)
```

Related Information

- The MySQL Reference Manual provides instructions to help you search for and modify JSON values.

- See CollectionModifyFunction for the full syntax definition.

20.3.3.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a database. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

Remove Documents Using Conditions

The example that follows passes a search condition to the `remove()` method. All documents matching the condition will be removed from the countryinfo collection. In this example, one document matches the condition.

```
mysql-js> db.countryinfo.remove("_id = 'SEA'")
Query OK, 1 item affected (0.02 sec)
```

Remove the First Document

To remove the first document in the countryinfo collection, use the `limit()` method with a value of 1.

```
mysql-js> db.countryinfo.remove("true").limit(1)
Query OK, 1 item affected (0.03 sec)
```

Remove the Last Document in an Order

The following example removes the last document in the countryinfo collection by country name.

```
mysql-js> db.countryinfo.remove("true").sort(["Name desc"]).limit(1)
Query OK, 1 item affected (0.02 sec)
```

Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove("true")` method without specifying any search condition.

Caution

Use care when you remove documents without specifying a search condition. This action will delete all documents from the collection.

Related Information

- See CollectionRemoveFunction for the full syntax definition.
- See Section 20.3.1, “Import Database Sample” for instructions to recreate the `world_x` database.

20.3.3.6 Create and Drop Indexes

Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query will perform better with an index:

```
mysql-js> db.countryinfo.find("demographics.Population < 100")
...[output removed]
```

```
8 documents in set (0.00 sec)
```

The `createIndex()` method creates an index that you can define as nonunique or unique. Use the `field()` method to chain the fields that should be indexed. The `execute()` method is required to create or drop an index.

In MySQL, the `_id` field is equivalent to a primary key by default.

Add a Nonunique Index

To create a nonunique index, pass to the `createIndex()` method an index name. Duplicate index names are prohibited.

In the following example, the first parameter of the `field()` method specifies the Population field inside the demographics object and the next parameter indicates that the field should be indexed as an Integer numeric value. The last parameter indicates whether the field should require the NOT NULL constraint. If the value is `false`, the field can contain `NULL` values.

```
mysql-js> db.countryinfo.createIndex("pop").
field("demographics.Population", "INTEGER", false).execute()
Query OK (0.04 sec)
```

Add a Unique Index

To create a unique index, pass to the `createIndex()` method an index name and the `mysqlx.IndexType.UNIQUE` type. Country `"Name"` is another common field in the countryinfo collection to index. In the following example, `"Text(40)"` represents the number of characters to index and `true` indicates that the field cannot contain any `NULL` values.

```
mysql-js> db.countryinfo.createIndex("name", mysqlx.IndexType.UNIQUE).
field("Name", "TEXT(40)", true).execute()
Query OK (0.04 sec)
```

Drop an Index

To drop an index, pass to the `dropIndex()` method the name of the index to drop. For example, you can drop the “pop” index as follows:

```
mysql-js> db.countryinfo.dropIndex("pop").execute()
Query OK (0.58 sec)
```

Related Information

- See Collection Index Management Functions for the full syntax definition.

20.3.4 Relational Tables

You can use MySQL Shell to manipulate not just JSON documents, but also relational tables.

In MySQL, each relational table is associated with a particular storage engine. The examples in this section use `InnoDB` tables in the `world_x` database.

Confirm the Schema

To show the value that is assigned to the schema variable, type `db`.

```
mysql-js> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable as follows:

```
mysql-js> \use world_x
```

Show All Tables

To display all relational tables in the `world_x` database, use the `getTables()` method on the schema object.

```
mysql-js> db.getTables()
{
    "city": <Table:city>,
    "country": <Table:country>,
    "countrylanguage": <Table:countrylanguage>
}
```

Basic Table Operations

Basic operations scoped by tables include:

Operation form	Description
`db.name.insert()`	The insert() method inserts one or more records into the named table.
`db.name.select()`	The select() method returns some or all records in the named table.
`db.name.update()`	The update() method updates records in the named table.
`db.name.delete()`	The delete() method deletes one or more records from the named table.

Related Information

- See Working with Relational Tables for a general overview.
- CRUD EBNF Definitions provides a complete list of operations.
- See Section 20.3.1, “Import Database Sample” for instructions on setting up the `world_x` database sample.

20.3.4.1 Insert Records into Tables

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.

Insert a Complete Record

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column in the table. For example, to add a new record to the city table in the `world_x` database, insert the following record and press **Enter** twice.

```
mysql-js> db.city.insert("ID", "Name", "CountryCode", "District", "Info").
values(null, "Olympia", "USA", "Washington", '{"Population": 5000}')
Query OK, 1 item affected (0.01 sec)
```

The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

Insert a Partial Record

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```
mysql-js> db.city.insert("ID", "Name", "CountryCode").
values(null, "Little Falls", "USA").values(null, "Happy Valley", "USA")
Query OK, 2 item affected (0.03 sec)
```

When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

Related Information

- See TableInsertFunction for the full syntax definition.

20.3.4.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: `OR` (`||`), `AND` (`&&`), `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Select All Records

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

Note

Limit the use of the empty `select()` method to interactive statements. Always use explicit column-name selections in your application code.

```
mysql-js> db.city.select()
+------+------------+-------------+------------+-------------------------+
| ID   | Name       | CountryCode | District   | Info                    |
+------+------------+-------------+------------+-------------------------+
|    1 | Kabul      | AFG         | Kabol      |{"Population": 1780000}  |
|    2 | Qandahar   | AFG         | Qandahar   |{"Population": 237500}   |
|    3 | Herat      | AFG         | Herat      |{"Population": 186800}   |
...    ...          ...           ...          ...
| 4079 | Rafah      | PSE         | Rafah      |{"Population": 92020}    |
+------+------- ----+-------------+------------+-------------------------+
4082 rows in set (0.01 sec)
```

An empty set (no matching records) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```
mysql-js> db.city.select(["Name", "CountryCode"])
+-------------------+-------------+
| Name              | CountryCode |
+-------------------+-------------+
| Kabul             | AFG         |
| Qandahar          | AFG         |
| Herat             | AFG         |
```

```
| Mazar-e-Sharif    | AFG         |
| Amsterdam         | NLD         |
...                 ...
| Rafah             | PSE         |
| Olympia           | USA         |
| Little Falls      | USA         |
| Happy Valley      | USA         |
+-------------------+-------------+
4082 rows in set (0.00 sec)
```

To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```
mysql-js> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%'")
+-------------------+-------------+
| Name              | CountryCode |
+-------------------+-------------+
| Zaanstad          | NLD         |
| Zoetermeer        | NLD         |
| Zwolle            | NLD         |
| Zenica            | BIH         |
| Zagazig           | EGY         |
| Zaragoza          | ESP         |
| Zamboanga         | PHL         |
| Zahedan           | IRN         |
| Zanjan            | IRN         |
| Zabol             | IRN         |
| Zama              | JPN         |
| Zhezqazghan       | KAZ         |
| Zhengzhou         | CHN         |
...                 ...
| Zeleznogorsk      | RUS         |
+-------------------+-------------+
59 rows in set (0.00 sec)
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of using "Name = 'Z%' " as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as *name*. Then include the placeholder and value in the `bind()` method as follows:

```
mysql-js> db.city.select(["Name", "CountryCode"]).
              where("Name like :name").bind("name", "Z%")
```

Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

Project Results

To issue a query using the `AND` operator, add the operator between search conditions in the `where()` method.

```
mysql-js> db.city.select(["Name", "CountryCode"]).
               where("Name like 'Z%' and CountryCode = 'CHN'")
+----------------+-------------+
| Name           | CountryCode |
+----------------+-------------+
| Zhengzhou      | CHN         |
```

```
| Zibo           | CHN         |
| Zhangjiakou    | CHN         |
| Zhuzhou        | CHN         |
| Zhangjiang     | CHN         |
| Zigong         | CHN         |
| Zaozhuang      | CHN         |
...              ...
| Zhangjiagang   | CHN         |
+----------------+-------------+
22 rows in set (0.01 sec)
```

To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of `AND` and `OR` operators.

```
mysql-js> db.city.select(["Name", "CountryCode"]).
where("Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS')")
+-------------------+-------------+
| Name              | CountryCode |
+-------------------+-------------+
| Zhengzhou         | CHN         |
| Zibo              | CHN         |
| Zhangjiakou       | CHN         |
| Zhuzhou           | CHN         |
...                 ...
| Zeleznogorsk      | RUS         |
+-------------------+-------------+
29 rows in set (0.01 sec)
```

Limit, Order, and Offset Results

You can apply the `limit()`, `orderBy()`, and `offSet()` methods to manage the number and order of records returned by the `select()` method.

To specify the number of records included in a result set, append the `limit()` method with a value to the `select()` method. For example, the following query returns the first five records in the country table.

```
mysql-js> db.country.select(["Code", "Name"]).limit(5)
+------+-------------+
| Code | Name        |
+------+-------------+
| ABW  | Aruba       |
| AFG  | Afghanistan |
| AGO  | Angola      |
| AIA  | Anguilla    |
| ALB  | Albania     |
+------+-------------+
5 rows in set (0.00 sec)
```

To specify an order for the results, append the `orderBy()` method to the `select()` method. Pass to the `orderBy()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the Name column and then returns the first three records in descending order .

```
mysql-js> db.country.select(["Code", "Name"]).orderBy(["Name desc"]).limit(3)
+------+------------+
| Code | Name       |
+------+------------+
| ZWE  | Zimbabwe   |
| ZMB  | Zambia     |
| YUG  | Yugoslavia |
+------+------------+
```

```
3 rows in set (0.00 sec)
```

By default, the `limit()` method starts from the first record in the table. You can use the `offset()` method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the `offset()` method a value of 1.

```
mysql-js> db.country.select(["Code", "Name"]).orderBy(["Name desc"]).limit(3).offset(1)
+------+------------+
| Code | Name       |
+------+------------+
| ZMB  | Zambia     |
| YUG  | Yugoslavia |
| YEM  | Yemen      |
+------+------------+
3 rows in set (0.00 sec)
```

Related Information

- The MySQL Reference Manual provides detailed documentation on functions and operators.
- See TableSelectFunction for the full syntax definition.

20.3.4.3 Update Tables

You can use the `update()` method to modify one or more records in a table. The `update()` method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the `set()` method the new city name. Then, pass to the `where()` method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```
mysql-js> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
Query OK, 1 item affected (0.04 sec)
```

Use the `select()` method to verify the change.

```
mysql-js> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where("Name = 'Beijing'")
+------+-----------+-------------+----------+-----------------------------+
| ID   | Name      | CountryCode | District | Info                        |
+------+-----------+-------------+----------+-----------------------------+
| 1891 | Beijing   | CHN         | Peking   | {"Population": 7472000}     |
+------+-----------+-------------+----------+-----------------------------+
1 row in set (0.00 sec)
```

Related Information

- See TableUpdateFunction for the full syntax definition.

20.3.4.4 Delete Tables

You can use the `delete()` method to remove some or all records from a table in a database. The X DevAPI provides additional methods to use with the `delete()` method to filter and order the records to be deleted.

Delete Records Using Conditions

The example that follows passes search conditions to the `delete()` method. All records matching the condition will be deleted from the city table. In this example, one record matches the condition.

```
mysql-js> db.city.delete().where("Name = 'Olympia'")
Query OK, 1 item affected (0.01 sec)
```

Delete the First Record

To delete the first record in the city table, use the `limit()` method with a value of 1.

```
mysql-js> db.city.delete().limit(1)
Query OK, 1 item affected (0.02 sec)
```

Delete All Records in a Table

You can delete all records in a table. To do so, use the `delete()` method without specifying a search condition.

Caution

Use care when you delete records without specifying a search condition. This action will delete all records from the table.

Drop a Table

The `dropCollection()` method is also used in MySQL Shell to drop a relational table from a database. For example, to drop the citytest table from the `world_x` database, type:

```
mysql-js> session.dropCollection("world_x", "citytest")
Query OK (0.04 sec)
```

Related Information

- See TableDeleteFunction for the full syntax definition.
- See Section 20.3.1, “Import Database Sample” for instructions to recreate the `world_x` database.

20.3.5 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native `JSON` data type.

Examples in this section use the city table in the `world_x` database.

city Table Description

The city table has five columns (or fields).

```
+---------------+------------+-------+-------+---------+------------------+
| Field         | Type       | Null  | Key   | Default | Extra            |
+---------------+------------+-------+-------+---------+------------------+
| ID            | int(11)    | NO    | PRI   | null    | auto_increment   |
| Name          | char(35)   | NO    |       |         |                  |
| CountryCode   | char(3)    | NO    |       |         |                  |
| District      | char(20)   | NO    |       |         |                  |
| Info          | json       | YES   |       | null    |                  |
+---------------+------------+-------+-------+---------+------------------+
```

Insert a Record

To insert a document into the column of a table, pass to the `values()` method a well-formed JSON document in the correct order. In the following example, a document is passed as the final value to be inserted into the Info column.

```
mysql-js> db.city.insert().
values(null, "San Francisco", "USA", "California", '{"Population":830000}')
Query OK, 1 item affected (0.01 sec)
```

Select a Record

You can issue a query with a search condition that evaluates document values in the expression.

```
mysql-js> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).
  where("CountryCode = :country and Info->'$.Population' > 1000000").
  bind('country', 'USA')
+------+----------------+-------------+----------------+-----------------------------+
| ID   | Name           | CountryCode | District       | Info                        |
+------+----------------+-------------+----------------+-----------------------------+
| 3793 | New York       | USA         | New York       | {"Population": 8008278}     |
| 3794 | Los Angeles    | USA         | California     | {"Population": 3694820}     |
| 3795 | Chicago        | USA         | Illinois       | {"Population": 2896016}     |
| 3796 | Houston        | USA         | Texas          | {"Population": 1953631}     |
| 3797 | Philadelphia   | USA         | Pennsylvania   | {"Population": 1517550}     |
| 3798 | Phoenix        | USA         | Arizona        | {"Population": 1321045}     |
| 3799 | San Diego      | USA         | California     | {"Population": 1223400}     |
| 3800 | Dallas         | USA         | Texas          | {"Population": 1188580}     |
| 3801 | San Antonio    | USA         | Texas          | {"Population": 1144646}     |
+------+----------------+-------------+----------------+-----------------------------+
9 rows in set (0.01 sec)
```

20.4 Python Quick-Start Guide: MySQL Shell for Document Store

This quick-start guide provides instructions to begin prototyping document store applications interactively with MySQL Shell. The guide includes the following topics:

- Introduction to MySQL functionality, MySQL Shell, and the `world_x` database sample.
- Operations to manage collections and documents.
- Operations to manage relational tables.
- Operations that apply to documents within tables.

Related Information

- MySQL Shell 8.0 (part of MySQL 8.0) provides more in-depth information about MySQL Shell.
- X DevAPI User Guide provides more examples of using X DevAPI.
- A JavaScript quick-start guide is also available.

20.4.1 Import Database Sample

The `world_x` database sample contains one JSON collection and a set of three relational tables:

- Collection
  - countryinfo: Information about countries in the world.
- Tables
  - country: Minimal information about countries of the world.
  - city: Information about some of the cities in those countries.
  - countrylanguage: Languages spoken in each country.

Requirements

To follow this quick-start guide you need a MySQL server with X Plugin installed, the default in 8.0, and MySQL Shell to use as the client. See Installing MySQL Shell. Start MySQL before you load the example `world_x` database for this guide.

Download and Import world_x Database

To prepare the `world_x` database sample, follow these steps:

1. Download world_x-db.zip.
2. Extract the installation archive to a temporary location such as `/tmp/`. Unpacking the archive results in a single file named `world_x.sql`.
3. Import the `world_x.sql` file to your database. You can either:
   - Start MySQL Shell in SQL mode and import the file by issuing:

     ```
     mysqlsh -u root --sql --file /tmp/world_x-db/world_x.sql
     Enter password: ****
     ```

   - Set MySQL Shell to SQL mode while it is running and source the schema file while MySQL Shell is running by issuing:

     ```
     \source /tmp/world_x-db/world_x.sql
     Switching to SQL mode... Commands end with ;
     \source /tmp/world_x-db/world_x.sql
     ```

   Replace `/tmp/` with the path to the `world_x.sql` file on your system. Enter your password when prompted. A non-root account can be used as long as the account has privileges to create new databases.

Related Information

- MySQL Shell Sessions explains session types.
- See Chapter 2, *Installing and Upgrading MySQL* for general installation assistance.

20.4.2 MySQL Shell

MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. JavaScript is the default processing mode. In most cases, you need an account to connect to the MySQL server instance.

Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. By default, MySQL Shell connects using X Protocol. You need to know the address of the MySQL server instance you plan to connect to.

If MySQL Shell is not already running, open a terminal window and issue:

```
mysqlsh name@localhost/world_x --py
```

Alternatively, if MySQL Shell is already running use the `\connect` command by issuing:

```
\connect name@host/world_x
```

You need to specify the address of your MySQL server instance which you want to connect MySQL Shell to. For example in the previous example:

- *name* represents the user name of your MySQL account.
- MySQL Shell prompts you for your password.
- The `--py` option starts MySQL Shell in Python mode. If you omit `--py`, MySQL Shell starts in JavaScript mode.
- The default schema for this session is the `world_x` database. For instructions on setting up the `world_x` database sample, see Section 20.4.1, “Import Database Sample”.

Once MySQL Shell opens, the `mysql-py>` prompt indicates that the active language for this session is Python.

```
mysql-py>
```

When you run `mysqlsh` without the host argument, MySQL Shell attempts to connect to the server instance running on the localhost interface on port 33060. For more information, see MySQL Shell Connections.

MySQL Shell supports input-line editing as follows:

- **left-arrow** and **right-arrow** keys move horizontally within the current input line.
- **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines.
- **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position.
- **Enter** sends the current input line to the server.

Get Help for MySQL Shell

Type `mysqlsh --help` at the prompt of your command interpreter for a list of command-line options.

```
mysqlsh --help
```

Type `\help` at the MySQL Shell prompt for a list of available commands and their descriptions.

```
mysql-py> \help
```

Type `\help` followed by a command name for detailed help about an individual MySQL Shell command. For example, to view help on the `\connect` command, type:

```
mysql-py> \help \connect
```

Quit MySQL Shell

To quit MySQL Shell, type the following command:

```
mysql-py> \quit
```

Related Information

- See Interactive Code Execution for an explanation of how interactive code execution works in MySQL Shell.
- See Getting Started with MySQL Shell to learn about session and connection alternatives.
- See Section 4.2.3, “Connecting Using a URI or Key-Value Pairs” to learn about specifying the location of a MySQL server.

20.4.3 Documents and Collections

In MySQL, collections contain JSON documents that you can add, find, update, and remove. Collections are containers within a schema that you can create, list, and drop.

The examples in this section use the countryinfo collection in the `world_x` database. For instructions on setting up the `world_x` database sample, see Section 20.4.1, “Import Database Sample”.

Documents

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for Python:

```
{"field1": "value", "field2" : 10, "field 3": null}
```

An array of documents consists of a set of documents separated by commas and enclosed within `[` and `]` characters.

- Simple array of documents for Python:

```
[{"Name": "Aruba", "_id": "ABW"}, {"Name": "Angola", "_id": "AGO"}]
```

MySQL supports the following Python value types in JSON documents:

- numbers (integer and floating point)
- strings
- boolean (False and True)
- None
- arrays of more JSON values
- nested (or embedded) objects of more JSON values

Collections

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.

The term schema is equivalent to a database, which means a group of database objects (as opposed to relational schema used to enforce structure and constraints over data). A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

- Basic objects include:

Object form	Description
`db`	`db` is a global variable assigned to the current active schema. When you want to run operations against the schema, for example to retrieve a collection, you use methods available for the `db` variable.
`db.get_collections()`	db.get_collections() holds a list of collections in the schema. Use the list to get references to collection objects, iterate over them, and so on.

- Basic operations scoped by collections include:

Operation form	Description
`db.name.add()`	The add() method inserts one document or a list of documents into the named collection.
`db.name.find()`	The find() method returns some or all documents in the named collection.
`db.name.modify()`	The modify() method updates documents in the named collection.
`db.name.remove()`	The remove() method deletes one document or a list of documents from the named collection.

Related Information

- See Working with Collections for a general overview.
- CRUD EBNF Definitions provides a complete list of operations.

20.4.3.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.

Confirm the Schema

To show the value that is assigned to the schema variable, issue:

```
mysql-py> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable by issuing:

```
mysql-py> \use world_x
```

Create a Collection

To create a new collection in an existing schema, use the `db` object's `createCollection()` method. The following example creates a collection called `flags` in the `world_x` database.

```
mysql-py> db.create_collection("flags")
```

The method returns a collection object.

```
<Collection:flags>
```

List Collections

To display all collections in the `world_x` database, use the `db` object's `get_collections()` method. Collections returned by the server you are currently connected to appear between brackets.

```
mysql-py> db.get_collections()
[
    <Collection:countryinfo>,
    <Collection:flags>
]
```

Drop a Collection

To drop an existing collection from a database, use the `db` object's `drop_collection()` method. For example, to drop the flags collection from the `world_x` database, type:

```
mysql-py> session.drop_collection("world_x", "flags")
```

The `drop_collection()` method is also used in MySQL Shell to drop a relational table from a database.

Related Information

- See Collection Objects for more examples.

20.4.3.2 Add Documents

Use the `add()` method to insert one document or a list of documents into an existing collection using MySQL Shell. All examples in this section use the countryinfo collection, which is provided in the `world_x` schema.

Add a Document

Insert the following document into the countryinfo collection. As this is multi-line content, press **Enter** twice to insert the document.

```
mysql-py> db.countryinfo.add(
 {
    GNP: .6,
    IndepYear: 1967,
    Name: "Sealand",
    demographics: {
        LifeExpectancy: 79,
        Population: 27
    },
    geography: {
        Continent: "Europe",
        Region: "British Islands",
        SurfaceArea: 193
    },
    government: {
        GovernmentForm: "Monarchy",
        HeadOfState: "Michael Bates"
    }
  }
)
```

The method returns the status of the operation.

Each document requires an identifier field called `_id`. The value of the `_id` field must be unique among all documents in the same collection. In MySQL 8.0.11 and higher, document IDs are generated by the server, not the client, so MySQL Shell does not automatically set an `_id` value. A MySQL server at 8.0.11 or higher sets an `_id` value if the document does not contain the `_id` field. A MySQL server at an earlier 8.0 release or at 5.7 does not set an `_id` value in this situation, so you must specify it explicitly. If you do not, MySQL Shell returns error 5115 `Document is missing a required field`.

Related Information

- See CollectionAddFunction for the full syntax definition.
- See Understanding Document IDs.

20.4.3.3 Find Documents

You can use the `find()` method to query for and return documents from a collection in a database. MySQL Shell provides additional methods to use with the `find()` method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: `OR` (`||`), `AND` (`&&`), `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Find All Documents in a Collection

To return all documents in a collection, use the `find()` method without specifying search conditions. For example, the following operation returns all documents in the countryinfo collection.

```
mysql-py> db.countryinfo.find()
[
     {
          "GNP": 828,
          "IndepYear": null,
          "Name": "Aruba",
          "_id": "ABW",
          "demographics": {
              "LifeExpectancy": 78.4000015258789,
              "Population": 103000
          },
          "geography": {
              "Continent": "North America",
              "Region": "Caribbean",
              "SurfaceArea": 193
          },
          "government": {
              "GovernmentForm": "Nonmetropolitan Territory of The Netherlands",
              "HeadOfState": "Beatrix"
          }
          ...
      }
 ]
240 documents in set (0.00 sec)
```

The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

You can include search conditions with the `find()` method. The syntax for expressions that form a search condition is the same as that of traditional MySQL Chapter 12, *Functions and Operators*. You must enclose all expressions in quotes.

All examples in this section use the countryinfo collection in the `world_x` database. For the sake of brevity, some of the examples do not display output.

A simple search condition could consist of the `Name` field and a value we know is in a document. The following example returns a single document:

```
mysql-py> db.countryinfo.find("Name = 'Australia'")
[
    {
        "GNP": 351182,
        "IndepYear": 1901,
        "Name": "Australia",
        "_id": "AUS",
        "demographics": {
            "LifeExpectancy": 79.80000305175781,
            "Population": 18886000
        },
        "geography": {
            "Continent": "Oceania",
```

```
            "Region": "Australia and New Zealand",
            "SurfaceArea": 7741220
        },
        "government": {
            "GovernmentForm": "Constitutional Monarchy, Federation",
            "HeadOfState": "Elisabeth II"
        }
    }
]
```

The following example searches for all countries that have a GNP higher than $500 billion. The countryinfo collection measures GNP in units of million.

```
mysql-py> db.countryinfo.find("GNP > 500000")
...[output removed]
10 documents in set (0.00 sec)
```

The Population field in the following query is embedded within the demographics object. To access the embedded field, use a period between demographics and Population to identify the relationship. Document and field names are case-sensitive.

```
mysql-py> db.countryinfo.find("GNP > 500000 and demographics.Population < 100000000")
...[output removed]
6 documents in set (0.00 sec)
```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than $30000. Search conditions can include arithmetic operators and most MySQL functions.

Note

Seven documents in the countryinfo collection have a population value of zero. Warning messages appear at the end of the output.

```
mysql-py> db.countryinfo.find("GNP*1000000/demographics.Population > 30000")
...[output removed]
9 documents in set, 7 warnings (0.00 sec)
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as *country*. Then use the `bind(placeholder, value)` method as follows:

```
mysql-py> db.countryinfo.find("Name = :country").bind("country", "Italy")
[
    {
        "GNP": 1161755,
        "IndepYear": 1861,
        "Name": "Italy",
        "_id": "ITA",
        "demographics": {
            "LifeExpectancy": 79,
            "Population": 57680000
        },
        "geography": {
            "Continent": "Europe",
            "Region": "Southern Europe",
            "SurfaceArea": 301316
        },
```

```
        "government": {
            "GovernmentForm": "Republic",
            "HeadOfState": "Carlo Azeglio Ciampi"
        }
    }
]
1 document in set (0.01 sec)
```

Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

You can use placeholders and the `bind()` method to create saved searches which you can then call with different values. For example to create a saved search for a country:

```
mysql-js> var myFind = db.countryinfo.find("Name = :country")
mysql-js> myFind.bind('country', 'France')
[
    {
        "GNP": 1424285,
        "IndepYear": 843,
        "Name": "France",
        "_id": "FRA",
        "demographics": {
            "LifeExpectancy": 78.80000305175781,
            "Population": 59225700
        },
        "geography": {
            "Continent": "Europe",
            "Region": "Western Europe",
            "SurfaceArea": 551500
        },
        "government": {
            "GovernmentForm": "Republic",
            "HeadOfState": "Jacques Chirac"
        }
    }
]
1 document in set (0.0028 sec)

mysql-js> myFind.bind('country', 'Germany')
[
    {
        "GNP": 2133367,
        "IndepYear": 1955,
        "Name": "Germany",
        "_id": "DEU",
        "demographics": {
            "LifeExpectancy": 77.4000015258789,
            "Population": 82164700
        },
        "geography": {
            "Continent": "Europe",
            "Region": "Western Europe",
            "SurfaceArea": 357022
        },
        "government": {
            "GovernmentForm": "Federal Republic",
            "HeadOfState": "Johannes Rau"
        }
    }
]
1 document in set (0.0026 sec)
```

Project Results

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the countryinfo collection matching the search conditions.

Use the `fields()` method to pass the list of fields to return.

```
mysql-py> db.countryinfo.find("GNP > 5000000").fields(["GNP", "Name"])
[
    {
        "GNP": 8510700,
        "Name": "United States"
    }
]
1 document in set (0.00 sec)
```

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new field values—with an expression that describes the document to return. For example, alter the names of the fields with the following expression to return only two documents.

```
mysql-py> db.countryinfo.find().\
fields(mysqlx.expr('{"Name": upper(Name), "GNPPerCapita": GNP*1000000/demographics.Population}')).\
limit(2)
[
    {
        "GNPPerCapita": 8038.834951456311,
        "Name": "ARUBA"
    },
    {
        "GNPPerCapita": 263.0281690140845,
        "Name": "AFGHANISTAN"
    }
]
2 documents in set (0.00 sec)
```

Limit, Sort, and Skip Results

You can apply the `limit()`, `sort()`, and `skip()` methods to manage the number and order of documents returned by the `find()` method.

To specify the number of documents included in a result set, append the `limit()` method with a value to the `find()` method. The following query returns the first five documents in the countryinfo collection.

```
mysql-py> db.countryinfo.find().limit(5)
... [output removed]
5 documents in set (0.00 sec)
```

To specify an order for the results, append the `sort()` method to the `find()` method. Pass to the `sort()` method a list of one or more fields to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all documents by the IndepYear field and then returns the first eight documents in descending order.

```
mysql-py> db.countryinfo.find().sort(["IndepYear desc"]).limit(8)
... [output removed]
8 documents in set (0.00 sec)
```

By default, the `limit()` method starts from the first document in the collection. You can use the `skip()` method to change the starting document. For example, to ignore the first document and return the next eight documents matching the condition, pass to the `skip()` method a value of 1.

```
mysql-py> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)
```

Related Information

- The MySQL Reference Manual provides detailed documentation on functions and operators.
- See CollectionFindFunction for the full syntax definition.

20.4.3.4 Modify Documents

You can use the `modify()` method to update one or more documents in a collection. The X DevAPI provides additional methods for use with the `modify()` method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.
- Bind, limit, and sort the documents to be modified.

Set and Unset Fields

The `modify()` method works by filtering a collection to include only the documents to be modified and then applying the operations that you specify to those documents.

In the following example, the `modify()` method uses the search condition to identify the document to change and then the `set()` method replaces two values within the nested demographics object.

```
mysql-py> db.countryinfo.modify("_id = 'SEA'").\
set("demographics", {"LifeExpectancy": 78, "Population": 28})
Query OK, 1 item affected (0.04 sec)
```

After you modify a document, use the `find()` method to verify the change.

To remove content from a document, use the `modify()` and `unset()` methods. For example, the following query removes the GNP from a document that matches the search condition.

```
mysql-py> db.countryinfo.modify("Name = 'Sealand'").unset("GNP")
Query OK, 1 item affected (0.01 sec)
```

Use the `find()` method to verify the change.

```
mysql-py> db.countryinfo.find("Name = 'Sealand'")
[
    {
        "IndepYear": 1967,
        "Name": "Sealand",
        "_id": "SEA",
        "demographics": {
            "LifeExpectancy": 78,
            "Population": 28
        },
        "geography": {
            "Continent": "Europe",
            "Region": "British Islands",
            "SurfaceArea": 193
        },
        "government": {
            "GovernmentForm": "Monarchy",
            "HeadOfState": "Michael Bates"
        }
    }
]
```

```
1 document in set (0.00 sec)
```

Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the `array_append()`, `array_insert()`, or `array_delete()` methods. The following examples modify the countryinfo collection to enable tracking of international airports.

The first example uses the `modify()` and `set()` methods to create a new Airports field in all documents.

Caution

Use care when you modify documents without specifying a search condition. This action will modify all documents in the collection.

```
mysql-py> db.countryinfo.modify(True).set("Airports", [])
Query OK, 240 items affected (0.07 sec)
```

With the Airports field added, the next example uses the `array_append()` method to add a new airport to one of the documents. *$.Airports* in the following example represents the Airports field of the current document.

```
mysql-py> db.countryinfo.modify("Name = 'France'").array_append("$.Airports", "ORY")
Query OK, 1 item affected (0.02 sec)
```

Use **`db.countryinfo.find("Name = 'France'")`** to see the change.

To insert an element at a different position in the array, use the `array_insert()` method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```
mysql-py> db.countryinfo.modify("Name = 'France'").array_insert("$.Airports[0]", "CDG")
Query OK, 1 item affected (0.04 sec)
```

To delete an element from the array, you must pass to the `array_delete()` method the index of the element to be deleted.

```
mysql-py> db.countryinfo.modify("Name = 'France'").array_delete("$.Airports[1]")
Query OK, 1 item affected (0.03 sec)
```

Related Information

- The MySQL Reference Manual provides instructions to help you search for and modify JSON values.
- See CollectionModifyFunction for the full syntax definition.

20.4.3.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a database. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

Remove Documents Using Conditions

The example that follows passes a search condition to the `remove()` method. All documents matching the condition will be removed from the countryinfo collection. In this example, one document matches the condition.

```
mysql-py> db.countryinfo.remove("_id = 'SEA'")
Query OK, 1 item affected (0.02 sec)
```

Remove the First Document

To remove the first document in the countryinfo collection, use the `limit()` method with a value of 1.

```
mysql-py> db.countryinfo.remove(True).limit(1)
Query OK, 1 item affected (0.03 sec)
```

Remove the Last Document in an Order

The following example removes the last document in the countryinfo collection by country name.

```
mysql-py> db.countryinfo.remove(True).sort(["Name desc"]).limit(1)
Query OK, 1 item affected (0.02 sec)
```

Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove(True)` method without specifying a search condition.

Caution

Use care when you remove documents without specifying a search condition. This action will delete all documents from the collection.

Related Information

- See CollectionRemoveFunction for the full syntax definition.
- See Section 20.4.1, “Import Database Sample” for instructions to recreate the `world_x` database.

20.4.3.6 Create and Drop Indexes

Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query will perform better with an index:

```
mysql-js> db.countryinfo.find("demographics.Population < 100")
...[output removed]
8 documents in set (0.00 sec)
```

The `create_index()` method creates an index that you can define as nonunique or unique. Use the `field()` method to chain the fields that should be indexed. The `execute()` method is required to create or drop an index.

In MySQL, the `_id` field is equivalent to a primary key by default.

Add a Nonunique Index

To create a nonunique index, pass to the `create_index()` method an index name. Duplicate index names are prohibited.

In the following example, the first parameter of the `field()` method specifies the Population field inside the demographics object and the next parameter indicates that the field should be indexed as an Integer numeric value. The last parameter indicates whether the field should require the NOT NULL constraint. If the value is `False`, the field can contain `NULL` values.

```
mysql-js> db.countryinfo.create_index("pop").\
```

```
field("demographics.Population", "INTEGER", False).execute()
Query OK (0.04 sec)
```

Add a Unique Index

To create a unique index, pass to the `create_index()` method an index name and the `mysqlx.IndexType.UNIQUE` type. Country `"Name"` is another common field in the countryinfo collection to index. In the following example, `"Text(40)"` represents the number of characters to index and `True` indicates that the field cannot contain any `NULL` values.

```
mysql-js> db.countryinfo.create_index("name", mysqlx.IndexType.UNIQUE).\
field("Name", "TEXT(40)", True).execute()
Query OK (0.04 sec)
```

Drop an Index

To drop an index, pass to the `drop_index()` method the name of the index to drop. For example, you can drop the “pop” index as follows:

```
mysql-js> db.countryinfo.drop_index("pop").execute()
Query OK (0.58 sec)
```

Related Information

- See Collection Index Management Functions for the full syntax definition.

20.4.4 Relational Tables

You can use MySQL Shell to manipulate not just JSON documents, but also relational tables.

In MySQL, each relational table is associated with a particular storage engine. The examples in this section use `InnoDB` tables in the `world_x` database.

Confirm the Schema

To show the value that is assigned to the schema variable, type `db`.

```
mysql-py> db
<Schema:world_x>
```

If the schema value is not the `Schema:world_x` database, then set the `db` variable as follows:

```
mysql-py> \use world_x
Schema `world_x` accessible through db.
```

Show All Tables

To display all relational tables in the `world_x` database, use the `get_tables()` method on the schema object.

```
mysql-py> db.get_tables()
{
    "city": <Table:city>,
    "country": <Table:country>,
    "countrylanguage": <Table:countrylanguage>
}
```

Basic Table Operations

Basic operations scoped by tables include:

Operation form	Description
`db.name.insert()`	The insert() method inserts one or more records into the named table.
`db.name.select()`	The select() method returns some or all records in the named table.
`db.name.update()`	The update() method updates records in the named table.
`db.name.delete()`	The delete() method deletes one or more records from the named table.

Related Information

- See Working with Relational Tables for a general overview.
- CRUD EBNF Definitions provides a complete list of operations.
- See Section 20.4.1, “Import Database Sample” for instructions on setting up the `world_x` database sample.

20.4.4.1 Insert Records into Tables

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.

Insert a Complete Record

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column. For example, to add a new record to the city table in the `world_x` database, insert the following record and press **Enter** twice.

```
mysql-py> db.city.insert("ID", "Name", "CountryCode", "District", "Info").\
values(None, "Olympia", "USA", "Washington", '{"Population": 5000}')
Query OK, 1 item affected (0.01 sec)
```

The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

Insert a Partial Record

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```
mysql-py> db.city.insert("ID", "Name", "CountryCode").\
values(None, "Little Falls", "USA").values(None, "Happy Valley", "USA")
Query OK, 2 item affected (0.03 sec)
```

When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

Related Information

- See TableInsertFunction for the full syntax definition.

20.4.4.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: `OR` (`||`), `AND` (`&&`), `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Select All Records

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

Note

Limit the use of the empty `select()` method to interactive statements. Always use explicit column-name selections in your application code.

```
mysql-py> db.city.select()
+------+------------+-------------+------------+-------------------------+
| ID   | Name       | CountryCode | District   | Info                    |
+------+------------+-------------+------------+-------------------------+
|    1 | Kabul      | AFG         | Kabol      |{"Population": 1780000}  |
|    2 | Qandahar   | AFG         | Qandahar   |{"Population": 237500}   |
|    3 | Herat      | AFG         | Herat      |{"Population": 186800}   |
...    ...          ...           ...          ...
| 4079 | Rafah      | PSE         | Rafah      |{"Population": 92020}    |
+------+------- ----+-------------+------------+-------------------------+
4082 rows in set (0.01 sec)
```

An empty set (no matching records) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```
mysql-py> db.city.select(["Name", "CountryCode"])
+-------------------+-------------+
| Name              | CountryCode |
+-------------------+-------------+
| Kabul             | AFG         |
| Qandahar          | AFG         |
| Herat             | AFG         |
| Mazar-e-Sharif    | AFG         |
| Amsterdam         | NLD         |
...                 ...
| Rafah             | PSE         |
| Olympia           | USA         |
| Little Falls      | USA         |
| Happy Valley      | USA         |
+-------------------+-------------+
4082 rows in set (0.00 sec)
```

To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```
mysql-py> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%'")
+-------------------+-------------+
| Name              | CountryCode |
+-------------------+-------------+
| Zaanstad          | NLD         |
| Zoetermeer        | NLD         |
| Zwolle            | NLD         |
```

```
| Zenica            | BIH         |
| Zagazig           | EGY         |
| Zaragoza          | ESP         |
| Zamboanga         | PHL         |
| Zahedan           | IRN         |
| Zanjan            | IRN         |
| Zabol             | IRN         |
| Zama              | JPN         |
| Zhezqazghan       | KAZ         |
| Zhengzhou         | CHN         |
...                 ...
| Zeleznogorsk      | RUS         |
+-------------------+-------------+
59 rows in set (0.00 sec)
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of using "Name = 'Z%' " as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as *name*. Then include the placeholder and value in the `bind()` method as follows:

```
mysql-py> db.city.select(["Name", "CountryCode"]).\
              where("Name like :name").bind("name", "Z%")
```

Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

Project Results

To issue a query using the `AND` operator, add the operator between search conditions in the `where()` method.

```
mysql-py> db.city.select(["Name", "CountryCode"]).\
               where("Name like 'Z%' and CountryCode = 'CHN'")
+----------------+-------------+
| Name           | CountryCode |
+----------------+-------------+
| Zhengzhou      | CHN         |
| Zibo           | CHN         |
| Zhangjiakou    | CHN         |
| Zhuzhou        | CHN         |
| Zhangjiang     | CHN         |
| Zigong         | CHN         |
| Zaozhuang      | CHN         |
...              ...
| Zhangjiagang   | CHN         |
+----------------+-------------+
22 rows in set (0.01 sec)
```

To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of `AND` and `OR` operators.

```
mysql-py> db.city.select(["Name", "CountryCode"]).\
where("Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS')")
+-------------------+-------------+
| Name              | CountryCode |
+-------------------+-------------+
| Zhengzhou         | CHN         |
```

```
| Zibo              | CHN         |
| Zhangjiakou       | CHN         |
| Zhuzhou           | CHN         |
...                 ...
| Zeleznogorsk      | RUS         |
+-------------------+-------------+
29 rows in set (0.01 sec)
```

Limit, Order, and Offset Results

You can apply the `limit()`, `order_by()`, and `offset()` methods to manage the number and order of records returned by the `select()` method.

To specify the number of records included in a result set, append the `limit()` method with a value to the `select()` method. For example, the following query returns the first five records in the country table.

```
mysql-py> db.country.select(["Code", "Name"]).limit(5)
+------+-------------+
| Code | Name        |
+------+-------------+
| ABW  | Aruba       |
| AFG  | Afghanistan |
| AGO  | Angola      |
| AIA  | Anguilla    |
| ALB  | Albania     |
+------+-------------+
5 rows in set (0.00 sec)
```

To specify an order for the results, append the `order_by()` method to the `select()` method. Pass to the `order_by()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the Name column and then returns the first three records in descending order .

```
mysql-py> db.country.select(["Code", "Name"]).order_by(["Name desc"]).limit(3)
+------+------------+
| Code | Name       |
+------+------------+
| ZWE  | Zimbabwe   |
| ZMB  | Zambia     |
| YUG  | Yugoslavia |
+------+------------+
3 rows in set (0.00 sec)
```

By default, the `limit()` method starts from the first record in the table. You can use the `offset()` method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the `offset()` method a value of 1.

```
mysql-py> db.country.select(["Code", "Name"]).order_by(["Name desc"]).limit(3).offset(1)
+------+------------+
| Code | Name       |
+------+------------+
| ZMB  | Zambia     |
| YUG  | Yugoslavia |
| YEM  | Yemen      |
+------+------------+
3 rows in set (0.00 sec)
```

Related Information

- The MySQL Reference Manual provides detailed documentation on functions and operators.
- See TableSelectFunction for the full syntax definition.

20.4.4.3 Update Tables

You can use the `update()` method to modify one or more records in a table. The `update()` method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the `set()` method the new city name. Then, pass to the `where()` method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```
mysql-py> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
Query OK, 1 item affected (0.04 sec)
```

Use the `select()` method to verify the change.

```
mysql-py> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where("Name = 'Beijing'")
+------+-----------+-------------+----------+----------------------------+
| ID   | Name      | CountryCode | District | Info                       |
+------+-----------+-------------+----------+----------------------------+
| 1891 | Beijing   | CHN         | Peking   | {"Population": 7472000}    |
+------+-----------+-------------+----------+----------------------------+
1 row in set (0.00 sec)
```

Related Information

- See TableUpdateFunction for the full syntax definition.

20.4.4.4 Delete Tables

You can use the `delete()` method to remove some or all records from a table in a database. The X DevAPI provides additional methods to use with the `delete()` method to filter and order the records to be deleted.

Delete Records Using Conditions

The example that follows passes search conditions to the `delete()` method. All records matching the condition will be deleted from the city table. In this example, one record matches the condition.

```
mysql-py> db.city.delete().where("Name = 'Olympia'")
Query OK, 1 item affected (0.01 sec)
```

Delete the First Record

To delete the first record in the city table, use the `limit()` method with a value of 1.

```
mysql-py> db.city.delete().limit(1)
Query OK, 1 item affected (0.02 sec)
```

Delete All Records in a Table

You can delete all records in a table. To do so, use the `delete()` method without specifying a search condition.

Caution

Use care when you delete records without specifying a search condition. This action will delete all records from the table.

Drop a Table

The `drop_collection()` method is also used in MySQL Shell to drop a relational table from a database. For example, to drop the citytest table from the `world_x` database, type:

```
mysql-py> session.drop_collection("world_x", "citytest")
Query OK (0.04 sec)
```

Related Information

- See TableDeleteFunction for the full syntax definition.
- See Section 20.4.1, “Import Database Sample” for instructions to recreate the `world_x` database.

20.4.5 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native `JSON` data type.

Examples in this section use the city table in the `world_x` database.

city Table Description

The city table has five columns (or fields).

```
+---------------+------------+-------+-------+---------+------------------+
| Field         | Type       | Null  | Key   | Default | Extra            |
+---------------+------------+-------+-------+---------+------------------+
| ID            | int(11)    | NO    | PRI   | null    | auto_increment   |
| Name          | char(35)   | NO    |       |         |                  |
| CountryCode   | char(3)    | NO    |       |         |                  |
| District      | char(20)   | NO    |       |         |                  |
| Info          | json       | YES   |       | null    |                  |
+---------------+------------+-------+-------+---------+------------------+
```

Insert a Record

To insert a document into the column of a table, pass to the `values()` method a well-formed JSON document in the correct order. In the following example, a document is passed as the final value to be inserted into the Info column.

```
mysql-py> db.city.insert().\
values(None, "San Francisco", "USA", "California", '{"Population":830000}')
Query OK, 1 item affected (0.01 sec)
```

Select a Record

You can issue a query with a search condition that evaluates document values in the expression.

```
mysql-py> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).\
  where("CountryCode = :country and Info->'$.Population' > 1000000").\
  bind('country', 'USA')
+------+---------------+-------------+----------------+-----------------------------+
| ID   | Name          | CountryCode | District       | Info                        |
+------+---------------+-------------+----------------+-----------------------------+
| 3793 | New York      | USA         | New York       | {"Population": 8008278}     |
| 3794 | Los Angeles   | USA         | California     | {"Population": 3694820}     |
| 3795 | Chicago       | USA         | Illinois       | {"Population": 2896016}     |
| 3796 | Houston       | USA         | Texas          | {"Population": 1953631}     |
| 3797 | Philadelphia  | USA         | Pennsylvania   | {"Population": 1517550}     |
| 3798 | Phoenix       | USA         | Arizona        | {"Population": 1321045}     |
| 3799 | San Diego     | USA         | California     | {"Population": 1223400}     |
| 3800 | Dallas        | USA         | Texas          | {"Population": 1188580}     |
| 3801 | San Antonio   | USA         | Texas          | {"Population": 1144646}     |
+------+---------------+-------------+----------------+-----------------------------+
9 rows in set (0.01 sec)
```

Related Information

- See Working with Relational Tables and Documents for a general overview.
- See Section 11.6, “The JSON Data Type” for a detailed description of the data type.

20.5 X Plugin

This section explains how to use, configure and monitor X Plugin.

20.5.1 Checking X Plugin Installation

Because X Plugin is enabled by default, installing or upgrading to MySQL 8 makes the plugin available. The following shows how to use MySQL Shell and a standard MySQL Client to check if the plugin is installed:

Check the X Plugin Installation

Verify that the X Plugin is installed.

An installed X Plugin is listed in the plugins list on the MySQL server, for example:

MySQL Shell command:

```
shell> mysqlsh -u user --sqlc -P 3306 -e "SHOW plugins"
```

MySQL Client program command:

```
shell> mysql -u user -p -e "SHOW plugins"
```

An example result if X Plugin is installed is highlighted here:

```
+----------------------------+----------+--------------------+---------+---------+
| Name                       | Status   | Type               | Library | License |
+----------------------------+----------+--------------------+---------+---------+

...

| mysqlx                     | ACTIVE   | DAEMON             | NULL    | GPL     |

...

+----------------------------+----------+--------------------+---------+---------+
```

20.5.2 Disabling X Plugin

The X Plugin can be disabled at startup by either setting `mysqlx=0` in your MySQL configuration file, or by passing in either `--mysqlx=0` or `--skip-mysqlx` when starting the MySQL server.

Alternatively, use the `-DWITH_MYSQLX=OFF` CMake option to compile MySQL Server without X Plugin.

20.5.3 Using Secure Connections with X Plugin

This section explains how to configure X Plugin to use secure connections. For more background information, see Section 6.4, “Using Encrypted Connections”.

X Plugin has its own SSL settings which can differ from those used with MySQL Server. This means that X Plugin can be configured with a different SSL key, certificate, and certificate authorities file than MySQL Server. Similarly, X Plugin has its own SSL status variables calculated independently from the MySQL Server SSL related variables. By default the X Plugin SSL configuration is taken

from the `mysqlx_ssl_*` variables, described at Section 20.5.5.2, “X Plugin Options and System Variables”. If no configuration is provided using the `mysqlx_ssl_*` variables, X Plugin falls back to using the MySQL Server SSL system variables. This means you can choose to either have separate SSL configurations for MySQL Protocol and X Protocol connections by configuring each separately, or share the SSL configuration between MySQL Protocol and X Protocol connections by only configuring the `ssl-*` variables.

On a server with X Plugin installed, to configure MySQL Protocol and X Protocol connections with separate SSL configurations use both the `ssl-*` and `mysqlx-ssl-*` variables in `my.cnf`:

```
[mysqld]
ssl-ca=ca1.pem
ssl-cert=server-cert1.pem
ssl-key=server-key1.pem

mysqlx-ssl-ca=ca2.pem
mysqlx-ssl-cert=server-cert2.pem
mysqlx-ssl-key=server-key2.pem
```

The available `mysqlx_ssl_*` variables mirror the SSL variables in MySQL Server, so the files and techniques described for configuring MySQL Server to use SSL at Section 6.4.1, “Configuring MySQL to Use Encrypted Connections” are relevant to configuring X Plugin to use secure connections.

You can configure the TLS versions used by X Protocol SSL connections using the `tls_version` system variable. The TLS version used by MySQL Protocol and X Protocol connections is therefore the same TLS version.

Encryption per connection is optional, but a specific user can be forced to use encryption for X Protocol and MySQL Protocol connections. You configure such a user by issuing a `GRANT` statement with the `REQUIRE` option. For more details see Section 13.7.1.6, “GRANT Syntax”. Alternatively all X Protocol and MySQL Protocol connections can be forced to use encryption by setting `require_secure_transport`.

20.5.4 Using X Plugin with the Caching SHA-2 Authentication Plugin

X Plugin supports MySQL accounts created with the Section 6.5.1.3, “Caching SHA-2 Pluggable Authentication” plugin. You can use X Plugin to authenticate against such accounts using non-SSL connections with `SHA256_MEMORY` authentication and SSL connections with `PLAIN` authentication.

Although the caching SHA-2 authentication plugin holds an authentication cache, to use such accounts with X Plugin the X Plugin authentication cache plugin named `mysqlx_cache_cleaner` is used. Like X Plugin, it is enabled by default.

Before you can use non-SSL connections to authenticate an account which uses the `caching_sha2_password` plugin, the account must have authenticated at least once over an SSL connection to store the password in the X Plugin authentication cache. This means that the first use of an account must be done using an SSL connection with the X Plugin authentication cache enabled. Once this initial authentication over SSL has succeeded non-SSL connections can be used.

20.5.5 X Plugin Options and Variables

This section describes the command options and system variables that configure X Plugin. If values specified at startup time are incorrect, X Plugin could fail to initialize properly and the server does not load it. In this case, the server could also produce error messages for other X Plugin settings because it cannot recognize them.

20.5.5.1 X Plugin Option and Variable Reference

This table provides an overview of the command options, and system and status variables provided by X Plugin.

Table 20.1 X Plugin Option and Variable Reference

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dy
mysqlx	Yes	Yes				
Mysqlx_aborted_clients				Yes	Global	No
Mysqlx_address				Yes	Global	No
mysqlx_bind_address	Yes	Yes	Yes		Global	No
Mysqlx_bytes_received				Yes	Both	No
Mysqlx_bytes_sent				Yes	Both	No
mysqlx_connect_timeout	Yes	Yes	Yes		Global	Yes
Mysqlx_connection_accept_errors				Yes	Both	No
Mysqlx_connection_errors				Yes	Both	No
Mysqlx_connections_accepted				Yes	Global	No
Mysqlx_connections_closed				Yes	Global	No
Mysqlx_connections_rejected				Yes	Global	No
Mysqlx_crud_create_view				Yes	Both	No
Mysqlx_crud_delete				Yes	Both	No
Mysqlx_crud_drop_view				Yes	Both	No
Mysqlx_crud_find				Yes	Both	No
Mysqlx_crud_insert				Yes	Both	No
Mysqlx_crud_modify_view				Yes	Both	No
Mysqlx_crud_update				Yes	Both	No
mysqlx_document_id_unique_prefix	Yes	Yes	Yes		Global	Yes
Mysqlx_errors_sent				Yes	Both	No
Mysqlx_errors_unknown_message_type				Yes	Both	No
Mysqlx_expect_close				Yes	Both	No
Mysqlx_expect_open				Yes	Both	No
mysqlx_idle_worker_thread_timeout	Yes	Yes	Yes		Global	Yes
Mysqlx_init_error				Yes	Both	No
mysqlx_interactive_timeout	Yes	Yes	Yes		Global	Yes
mysqlx_max_allowed_packet	Yes	Yes	Yes		Global	Yes
mysqlx_max_connections	Yes	Yes	Yes		Global	Yes
mysqlx_min_worker_threads	Yes	Yes	Yes		Global	Yes
Mysqlx_notice_global_sent				Yes	Both	No
Mysqlx_notice_other_sent				Yes	Both	No
Mysqlx_notice_warning_sent				Yes	Both	No
Mysqlx_notified_by_group_replication				Yes	Both	No
Mysqlx_port				Yes	Global	No
mysqlx_port	Yes	Yes	Yes		Global	No
mysqlx_port_open_timeout	Yes	Yes	Yes		Global	No
mysqlx_read_timeout	Yes	Yes	Yes		Session	Yes
Mysqlx_rows_sent				Yes	Both	No
Mysqlx_sessions				Yes	Global	No

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynam
Mysqlx_sessions_accepted				Yes	Global	No
Mysqlx_sessions_closed				Yes	Global	No
Mysqlx_sessions_fatal_error				Yes	Global	No
Mysqlx_sessions_killed				Yes	Global	No
Mysqlx_sessions_rejected				Yes	Global	No
Mysqlx_socket				Yes	Global	No
mysqlx_socket	Yes	Yes	Yes		Global	No
Mysqlx_ssl_accept_renegotiates				Yes	Global	No
Mysqlx_ssl_accepts				Yes	Global	No
Mysqlx_ssl_active				Yes	Both	No
mysqlx_ssl_ca	Yes	Yes	Yes		Global	No
mysqlx_ssl_capath	Yes	Yes	Yes		Global	No
mysqlx_ssl_cert	Yes	Yes	Yes		Global	No
Mysqlx_ssl_cipher				Yes	Both	No
mysqlx_ssl_cipher	Yes	Yes	Yes		Global	No
Mysqlx_ssl_cipher_list				Yes	Both	No
mysqlx_ssl_crl	Yes	Yes	Yes		Global	No
mysqlx_ssl_crlpath	Yes	Yes	Yes		Global	No
Mysqlx_ssl_ctx_verify_depth				Yes	Both	No
Mysqlx_ssl_ctx_verify_mode				Yes	Both	No
Mysqlx_ssl_finished_accepts				Yes	Global	No
mysqlx_ssl_key	Yes	Yes	Yes		Global	No
Mysqlx_ssl_server_not_after				Yes	Global	No
Mysqlx_ssl_server_not_before				Yes	Global	No
Mysqlx_ssl_verify_depth				Yes	Global	No
Mysqlx_ssl_verify_mode				Yes	Global	No
Mysqlx_ssl_version				Yes	Both	No
Mysqlx_stmt_create_collection				Yes	Both	No
Mysqlx_stmt_create_collection_index				Yes	Both	No
Mysqlx_stmt_disable_notices				Yes	Both	No
Mysqlx_stmt_drop_collection				Yes	Both	No
Mysqlx_stmt_drop_collection_index				Yes	Both	No
Mysqlx_stmt_enable_notices				Yes	Both	No
Mysqlx_stmt_ensure_collection				Yes	Both	No
Mysqlx_stmt_execute_mysqlx				Yes	Both	No
Mysqlx_stmt_execute_sql				Yes	Both	No
Mysqlx_stmt_execute_xplugin				Yes	Both	No
Mysqlx_stmt_kill_client				Yes	Both	No
Mysqlx_stmt_list_clients				Yes	Both	No
Mysqlx_stmt_list_notices				Yes	Both	No
Mysqlx_stmt_list_objects				Yes	Both	No

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dy
Mysqlx_stmt_ping				Yes	Both	No
mysqlx_wait_timeout	Yes	Yes	Yes		Session	Yes
Mysqlx_worker_threads				Yes	Global	No
Mysqlx_worker_threads_active				Yes	Global	No
mysqlx_write_timeout	Yes	Yes	Yes		Session	Yes

20.5.5.2 X Plugin Options and System Variables

To control activation of X Plugin, use this option:

- `--mysqlx[=value]`

Property	Value
Command-Line Format	`--mysqlx[=value]`
Introduced	8.0.11
Type	Enumeration
Default Value	`ON`

Valid Values	`ON`
	`OFF`
	`FORCE`
	`FORCE_PLUS_PERMANENT`

This option controls how the server loads X Plugin at startup. In MySQL 8.0, X Plugin is enabled by default, but this option may be used to control its activation state.

The option value should be one of those available for plugin-loading options, as described in Section 5.6.1, “Installing and Uninstalling Plugins”.

If X Plugin is enabled, it exposes several system variables that permit control over its operation:

- `mysqlx_bind_address`

Property	Value
Command-Line Format	`--mysqlx-bind-address=value`
System Variable	`mysqlx_bind_address`
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	`*`

The network address on which X Plugin listens for TCP/IP connections. This variable is not dynamic and can be configured only at startup. This is the X Plugin equivalent of the `--bind-address` server option; see that option for more information.

If `mysqlx_bind_address` is specified, its value must satisfy these requirements:

- The value must be a single non-wildcard IP address or host name, or one of the wildcard address formats that permit listening on multiple network interfaces (`*`, `0.0.0.0`, or `::`).

- As of MySQL 8.0.16, the value may include a network namespace specifier.

An IP address can be specified as an IPv4 or IPv6 address. If the value is a host name, X Plugin resolves the name to an IP address and binds to that address. If a host name resolves to multiple IP addresses, X Plugin uses the first IPv4 address if there are any, or the first IPv6 address otherwise.

X Plugin treats different types of addresses as follows:

- If the address is `*`, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections for X Plugin. This value is the default.
- If the address is `0.0.0.0`, X Plugin accepts TCP/IP connections on all server host IPv4 interfaces.
- If the address is `::`, X Plugin accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces.
- If the address is an IPv4-mapped address, X Plugin accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if X Plugin is bound to `::ffff:127.0.0.1`, a client such as MySQL Shell can connect using `--host=127.0.0.1` or `--host=::ffff:127.0.0.1`.
- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `::1`), X Plugin accepts TCP/IP connections only for that IPv4 or IPv6 address.

These rules apply to specifying a network namespace for an address:

- A network namespace can be specified for an IP address or a host name.
- A network namespace cannot be specified for a wildcard IP address.
- For a given address, the network namespace is optional. If given, it must be specified as a */ns* suffix immediately following the address.
- An address with no */ns* suffix uses the host system global namespace. The global namespace is therefore the default.
- An address with a */ns* suffix uses the namespace named *ns*.
- The host system must support network namespaces and each named namespace must previously have been set up. Naming a nonexistent namespace produces an error.

For additional information about network namespaces, see Section 5.1.13, “Network Namespace Support”.

If binding to the address fails, X Plugin produces an error and the server does not load it.

- `mysqlx_connect_timeout`

Property	Value
Command-Line Format	`--mysqlx-connect-timeout=value`
System Variable	`mysqlx_connect_timeout`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`30`
Minimum Value	`1`

Property	Value
Maximum Value	`1000000000`

The number of seconds X Plugin waits for the first packet to be received from newly connected clients. This is the X Plugin equivalent of `connect_timeout`; see that variable for more information.

- `mysqlx_document_id_unique_prefix`

Property	Value
Command-Line Format	`--mysqlx-document-id-unique-prefix=value`
System Variable	`mysqlx_document_id_unique_prefix`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`0`
Minimum Value	`0`
Maximum Value	`65535`

Sets the first 4 bytes of document IDs generated by the server when documents are added to a collection. By setting this variable to a unique value per instance, you can ensure document IDs are unique across instances. See Understanding Document IDs.

- `mysqlx_idle_worker_thread_timeout`

Property	Value
Command-Line Format	`--mysqlx-idle-worker-thread-timeout=value`
System Variable	`mysqlx_idle_worker_thread_timeout`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`60`
Minimum Value	`0`
Maximum Value	`3600`

The number of seconds after which idle worker threads are terminated.

- `mysqlx_interactive_timeout`

Property	Value
Command-Line Format	`--mysqlx-interactive-timeout=value`
Introduced	8.0.4
System Variable	`mysqlx_interactive_timeout`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No

Property	Value
Type	Integer
Default Value	`28800`
Minimum Value	`1`
Maximum Value	`2147483`

The default value of the `mysqlx_wait_timeout` session variable for interactive clients. (The number of seconds to wait for interactive clients to timeout.)

- `mysqlx_max_allowed_packet`

Property	Value
Command-Line Format	`--mysqlx-max-allowed-packet=value`
System Variable	`mysqlx_max_allowed_packet`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`67108864`
Minimum Value	`512`
Maximum Value	`1073741824`

The maximum size of network packets that can be received by X Plugin. This is the X Plugin equivalent of `max_allowed_packet`; see that variable for more information.

- `mysqlx_max_connections`

Property	Value
Command-Line Format	`--mysqlx-max-connections=value`
System Variable	`mysqlx_max_connections`
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`100`
Minimum Value	`1`
Maximum Value	`65535`

The maximum number of concurrent client connections X Plugin can accept. This is the X Plugin equivalent of `max_connections`; see that variable for more information.

For modifications to this variable, if the new value is smaller than the current number of connections, the new limit is taken into account only for new connections.

- `mysqlx_min_worker_threads`

Property	Value
Command-Line Format	`--mysqlx-min-worker-threads=value`
System Variable	`mysqlx_min_worker_threads`

Property	Value
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	1
Maximum Value	100

The minimum number of worker threads used by X Plugin for handling client requests.

- mysqlx_port

Property	Value
Command-Line Format	--mysqlx-port=value
System Variable	mysqlx_port
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	33060
Minimum Value	1
Maximum Value	65535

The network port on which X Plugin listens for TCP/IP connections. This is the X Plugin equivalent of port; see that variable for more information.

- mysqlx_port_open_timeout

Property	Value
Command-Line Format	--mysqlx-port-open-timeout=value
System Variable	mysqlx_port_open_timeout
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	120

The number of seconds X Plugin waits for a TCP/IP port to become free.

- mysqlx_read_timeout

Property	Value
Command-Line Format	--mysqlx-read-timeout=value
Introduced	8.0.4
System Variable	mysqlx_read_timeout

Property	Value
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	28800
Minimum Value	30
Maximum Value	2147483

The number of seconds that X Plugin waits for blocking read operations to complete. After this time, if the read operation is not successful, the connection is aborted.

- mysqlx_socket

Property	Value
Command-Line Format	--mysqlx-socket=file_name
System Variable	mysqlx_socket
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	/tmp/mysqlx.sock

The path to a Unix socket file which X Plugin uses for connections. This setting is only used by MySQL Server when running on Unix operating systems. Clients can use this socket to connect to MySQL Server using X Plugin.

The default mysqlx_socket path and file name is based on the default path and file name for the main socket file for MySQL Server, with the addition of an x appended to the file name. The default path and file name for the main socket file is /tmp/mysql.sock, therefore the default path and file name for the X Plugin socket file is /tmp/mysqlx.sock.

If you specify an alternative path and file name for the main socket file at server startup using the socket system variable, this does not affect the default for the X Plugin socket file. In this situation, if you want to store both sockets at a single path, you must set the mysqlx_socket system variable as well. For example in a configuration file:

```
socket=/home/sockets/mysqld/mysql.sock
mysqlx_socket=/home/sockets/xplugin/xplugin.sock
```

If you change the default path and file name for the main socket file at compile time using the MYSQL_UNIX_ADDR compile option, this does affect the default for the X Plugin socket file, which is formed by appending an x to the MYSQL_UNIX_ADDR file name. If you want to set a different default for the X Plugin socket file at compile time, use the MYSQLX_UNIX_ADDR compile option.

The MYSQLX_UNIX_PORT environment variable can also be used to set a default for the X Plugin socket file at server startup (see Section 4.9, “MySQL Program Environment Variables”). If you set this environment variable, it overrides the compiled MYSQLX_UNIX_ADDR value, but is overridden by the mysqlx_socket value.

- mysqlx_ssl_ca

Property	Value
Command-Line Format	`--mysqlx-ssl-ca=file_name`
System Variable	`mysqlx_ssl_ca`
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

This is the X Plugin equivalent of `ssl_ca`; see that variable for more information.

- `mysqlx_ssl_capath`

Property	Value
Command-Line Format	`--mysqlx-ssl-capath=dir_name`
System Variable	`mysqlx_ssl_capath`
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

This is the X Plugin equivalent of `ssl_capath`; see that variable for more information.

- `mysqlx_ssl_cert`

Property	Value
Command-Line Format	`--mysqlx-ssl-cert=name`
System Variable	`mysqlx_ssl_cert`
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

This is the X Plugin equivalent of `ssl_cert`; see that variable for more information.

- `mysqlx_ssl_cipher`

Property	Value
Command-Line Format	`--mysqlx-ssl-cipher=name`
System Variable	`mysqlx_ssl_cipher`
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String

The SSL cipher to use for X Protocol connections. This is the X Plugin equivalent of `ssl_cipher`; see that variable for more information.

- `mysqlx_ssl_crl`

Property	Value
Command-Line Format	`--mysqlx-ssl-crl=file_name`
System Variable	`mysqlx_ssl_crl`
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

This is the X Plugin equivalent of `ssl_crl`; see that variable for more information.

- `mysqlx_ssl_crlpath`

Property	Value
Command-Line Format	`--mysqlx-ssl-crlpath=dir_name`
System Variable	`mysqlx_ssl_crlpath`
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name

This is the X Plugin equivalent of `ssl_crlpath`; see that variable for more information.

- `mysqlx_ssl_key`

Property	Value
Command-Line Format	`--mysqlx-ssl-key=file_name`
System Variable	`mysqlx_ssl_key`
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name

This is the X Plugin equivalent of `ssl_key`; see that variable for more information.

- `mysqlx_wait_timeout`

Property	Value
Command-Line Format	`--mysqlx-wait-timeout=value`
Introduced	8.0.4
System Variable	`mysqlx_wait_timeout`
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`28800`
Minimum Value	`1`
Maximum Value	`2147483`

The number of seconds that X Plugin waits for activity on a connection. After this time, if the read operation is not successful, the connection is aborted. If the client is noninteractive, the initial value of the session variable is copied from the global `mysqlx_wait_timeout` variable. For interactive clients, the initial value is copied from the session `mysqlx_interactive_timeout`.

- `mysqlx_write_timeout`

Property	Value
Command-Line Format	`--mysqlx-write-timeout=value`
Introduced	8.0.4
System Variable	`mysqlx_write_timeout`
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	`60`
Minimum Value	`1`
Maximum Value	`2147483`

The number of seconds that X Plugin waits for blocking write operations to complete. After this time, if the write operation is not successful, the connection is aborted.

20.5.6 Monitoring X Plugin

This section describes how to monitor X Plugin. There are two available methods of monitoring, using Performance Schema tables or status variables.

20.5.6.1 Status Variables for X Plugin

The status variables have the following meanings.

- `Mysqlx_aborted_clients`

  The number of clients that were disconnected because of an input or output error.

- `Mysqlx_address`

  The network address which X Plugin is bound to. If the bind has failed, or if the `skip_networking` option has been used, the value shows `UNDEFINED`.

- `Mysqlx_bytes_received`

  The number of bytes received through the network.

- `Mysqlx_bytes_sent`

  The number of bytes sent through the network.

- `Mysqlx_connection_accept_errors`

  The number of connections which have caused accept errors.

- `Mysqlx_connection_errors`

  The number of connections which have caused errors.

- `Mysqlx_connections_accepted`

The number of connections which have been accepted.

- `Mysqlx_connections_closed`

  The number of connections which have been closed.

- `Mysqlx_connections_rejected`

  The number of connections which have been rejected.

- `Mysqlx_crud_create_view`

  The number of create view requests received.

- `Mysqlx_crud_delete`

  The number of delete requests received.

- `Mysqlx_crud_drop_view`

  The number of drop view requests received.

- `Mysqlx_crud_find`

  The number of find requests received.

- `Mysqlx_crud_insert`

  The number of insert requests received.

- `Mysqlx_crud_modify_view`

  The number of modify view requests received.

- `Mysqlx_crud_update`

  The number of update requests received.

- `Mysqlx_cursor_close`

  The number of cursor-close messages received

- `Mysqlx_cursor_fetch`

  The number of cursor-fetch messages received

- `Mysqlx_cursor_open`

  The number of cursor-open messages received

- `Mysqlx_errors_sent`

  The number of errors sent to clients.

- `Mysqlx_expect_close`

  The number of expectation blocks closed.

- `Mysqlx_expect_open`

  The number of expectation blocks opened.

- `Mysqlx_init_error`

The number of errors during initialisation.

- `Mysqlx_notice_global_sent`

  The number of global notifications sent to clients.

- `Mysqlx_notice_other_sent`

  The number of other types of notices sent back to clients.

- `Mysqlx_notice_warning_sent`

  The number of warning notices sent back to clients.

- `Mysqlx_notified_by_group_replication`

  Number of Group Replication notifications sent to clients

- `Mysqlx_port`

  The TCP port which X Plugin is listening to. If a network bind has failed, or if the `--skip-networking` option has been used, the value shows `UNDEFINED`.

- `Mysqlx_prep_deallocate`

  The number of prepared-statement-deallocate messages received

- `Mysqlx_prep_execute`

  The number of prepared-statement-execute messages received

- `Mysqlx_prep_prepare`

  The number of prepared-statement messages received

- `Mysqlx_rows_sent`

  The number of rows sent back to clients.

- `Mysqlx_sessions`

  The number of sessions that have been opened.

- `Mysqlx_sessions_accepted`

  The number of session attempts which have been accepted.

- `Mysqlx_sessions_closed`

  The number of sessions that have been closed.

- `Mysqlx_sessions_fatal_error`

  The number of sessions that have closed with a fatal error.

- `Mysqlx_sessions_killed`

  The number of sessions which have been killed.

- `Mysqlx_sessions_rejected`

  The number of session attempts which have been rejected.

- `Mysqlx_socket`

The Unix socket which X Plugin is listening to.

- `Mysqlx_ssl_accept_renegotiates`

  The number of negotiations needed to establish the connection.

- `Mysqlx_ssl_accepts`

  The number of accepted SSL connections.

- `Mysqlx_ssl_active`

  If SSL is active.

- `Mysqlx_ssl_cipher`

  The current SSL cipher (empty for non-SSL connections).

- `Mysqlx_ssl_cipher_list`

  A list of possible SSL ciphers (empty for non-SSL connections).

- `Mysqlx_ssl_ctx_verify_depth`

  The certificate verification depth limit currently set in ctx.

- `Mysqlx_ssl_ctx_verify_mode`

  The certificate verification mode currently set in ctx.

- `Mysqlx_ssl_finished_accepts`

  The number of successful SSL connections to the server.

- `Mysqlx_ssl_server_not_after`

  The last date for which the SSL certificate is valid.

- `Mysqlx_ssl_server_not_before`

  The first date for which the SSL certificate is valid.

- `Mysqlx_ssl_verify_depth`

  The certificate verification depth for SSL connections.

- `Mysqlx_ssl_verify_mode`

  The certificate verification mode for SSL connections.

- `Mysqlx_ssl_version`

  The name of the protocol used for SSL connections.

- `Mysqlx_stmt_create_collection`

  The number of create collection statements received.

- `Mysqlx_stmt_create_collection_index`

  The number of create collection index statements received.

- `Mysqlx_stmt_disable_notices`

The number of disable notice statements received.

- `Mysqlx_stmt_drop_collection`

  The number of drop collection statements received.

- `Mysqlx_stmt_drop_collection_index`

  The number of drop collection index statements received.

- `Mysqlx_stmt_enable_notices`

  The number of enable notice statements received.

- `Mysqlx_stmt_ensure_collection`

  The number of ensure collection statements received.

- `Mysqlx_stmt_execute_mysqlx`

  The number of StmtExecute messages received with namespace set to `mysqlx`.

- `Mysqlx_stmt_execute_sql`

  The number of StmtExecute requests received for the SQL namespace.

- `Mysqlx_stmt_execute_xplugin`

  The number of StmtExecute requests received for the X Plugin namespace.

- `Mysqlx_stmt_kill_client`

  The number of kill client statements received.

- `Mysqlx_stmt_list_clients`

  The number of list client statements received.

- `Mysqlx_stmt_list_notices`

  The number of list notice statements received.

- `Mysqlx_stmt_list_objects`

  The number of list object statements received.

- `Mysqlx_stmt_ping`

  The number of ping statements received.

- `Mysqlx_worker_threads`

  The number of worker threads available.

- `Mysqlx_worker_threads_active`

  The number of worker threads currently used.

Chapter 21 InnoDB Cluster

Table of Contents

21.1 Introducing InnoDB Cluster 3247
21.2 Creating an InnoDB Cluster 3249
21.2.1 Deployment Scenarios 3249
21.2.2 InnoDB Cluster Requirements 3250
21.2.3 Methods of Installing 3250
21.2.4 Production Deployment of InnoDB Cluster 3251
21.2.5 Sandbox Deployment of InnoDB Cluster 3260
21.2.6 Adopting a Group Replication Deployment 3263
21.3 Using MySQL Router with InnoDB Cluster 3264
21.4 Working with InnoDB Cluster 3267
21.5 Known Limitations 3288

This chapter covers MySQL InnoDB cluster, which combines MySQL technologies to enable you to create highly available clusters of MySQL server instances.

21.1 Introducing InnoDB Cluster

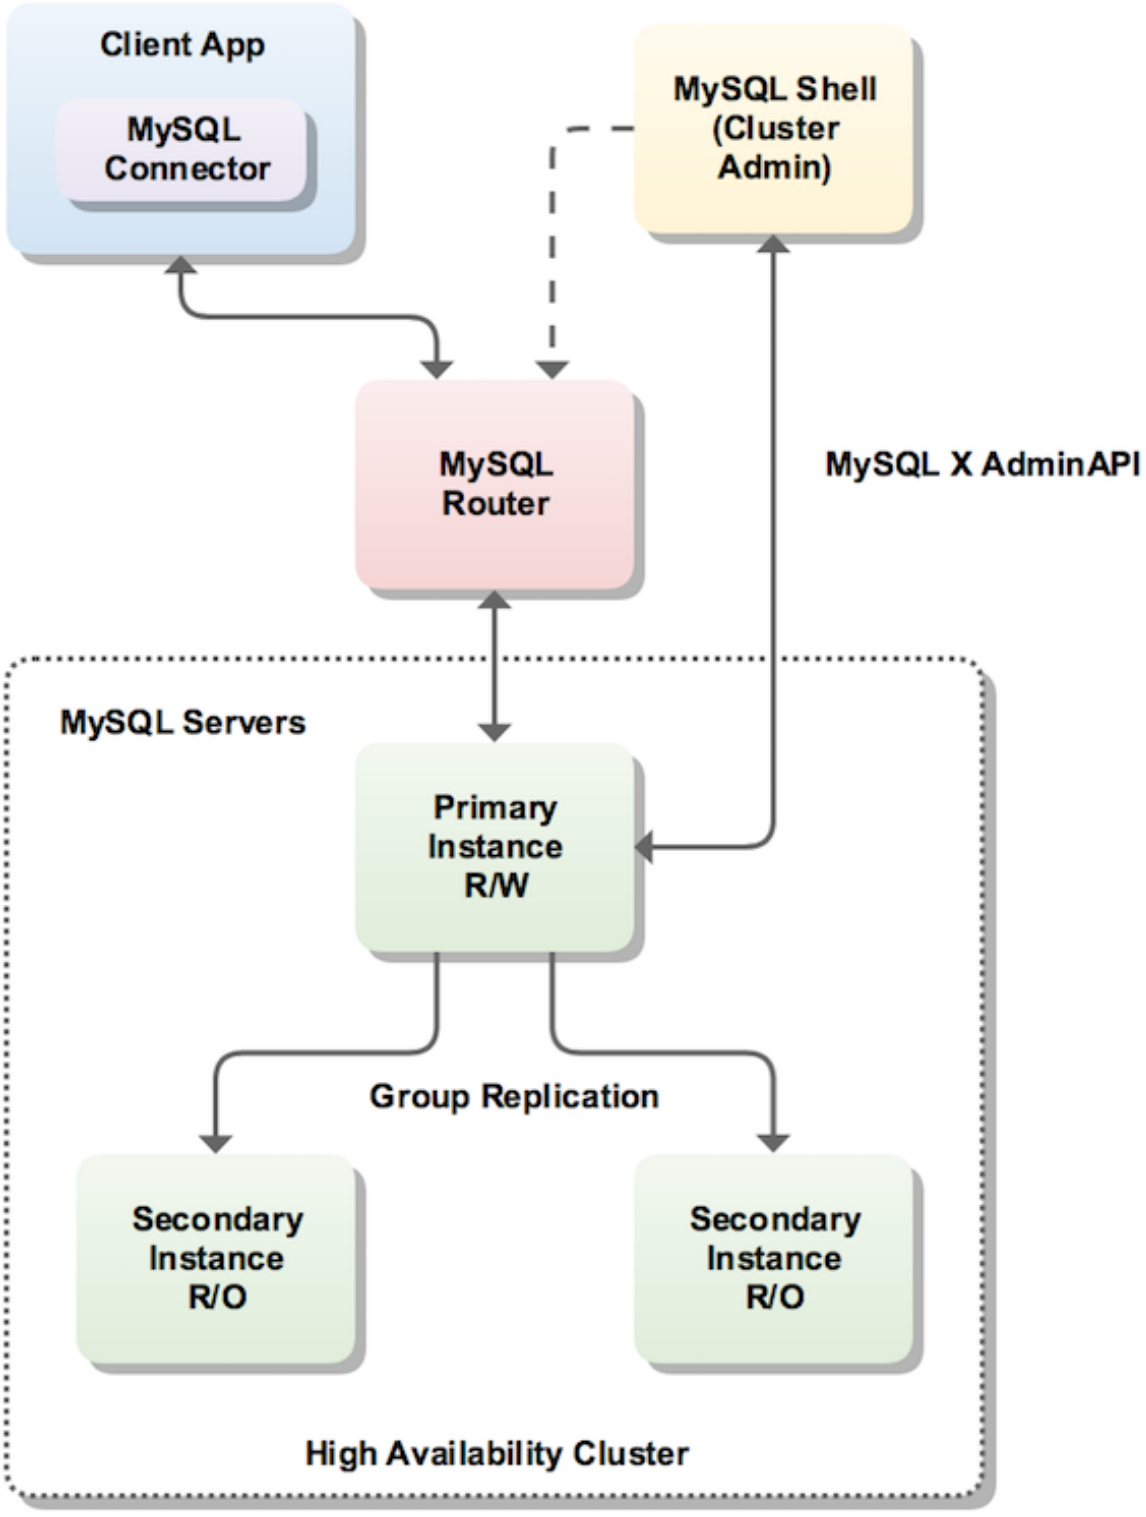
MySQL InnoDB cluster provides a complete high availability solution for MySQL. MySQL Shell includes AdminAPI which enables you to easily configure and administer a group of at least three MySQL server instances to function as an InnoDB cluster. Each MySQL server instance runs MySQL Group Replication, which provides the mechanism to replicate data within InnoDB clusters, with built-in failover. AdminAPI removes the need to work directly with Group Replication in InnoDB clusters, but for more information see Chapter 18, *Group Replication* which explains the details. MySQL Router can automatically configure itself based on the cluster you deploy, connecting client applications transparently to the server instances. In the event of an unexpected failure of a server instance the cluster reconfigures automatically. In the default single-primary mode, an InnoDB cluster has a single read-write server instance - the primary. Multiple secondary server instances are replicas of the primary. If the primary fails, a secondary is automatically promoted to the role of primary. MySQL Router detects this and forwards client applications to the new primary. Advanced users can also configure a cluster to have multiple-primaries.

Important

InnoDB cluster does not provide support for MySQL NDB Cluster. NDB Cluster depends on the `NDB` storage engine as well as a number of programs specific to NDB Cluster which are not furnished with MySQL Server 8.0; `NDB` is available only as part of the MySQL NDB Cluster distribution. In addition, the MySQL server binary (`mysqld`) that is supplied with MySQL Server 8.0 cannot be used with NDB Cluster. For more information about MySQL NDB Cluster, see Chapter 22, *MySQL NDB Cluster 8.0*. Section 22.1.6, “MySQL Server Using InnoDB Compared with NDB Cluster”, provides information about the differences between the `InnoDB` and `NDB` storage engines.

The following diagram shows an overview of how these technologies work together:

Figure 21.1 InnoDB cluster overview



Using AdminAPI

MySQL Shell includes the AdminAPI, which is accessed through the `dba` global variable and its associated methods. The `dba` variable's methods enable you to deploy, configure, and administer InnoDB clusters. For example, use the `dba.createCluster()` method to create an InnoDB cluster.

Important

MySQL Shell enables you to connect to servers over a socket connection, but AdminAPI requires TCP connections to a server instance. Socket based connections are not supported in AdminAPI.

MySQL Shell provides online help for the AdminAPI. To list all available `dba` commands, use the `dba.help()` method. For online help on a specific method, use the general format `object.help('methodname')`. For example:

```
mysql-js> dba.help('getCluster')

Retrieves a cluster from the Metadata Store.

SYNTAX

  dba.getCluster([name][, options])

WHERE

  name: Parameter to specify the name of the cluster to be returned.
  options: Dictionary with additional options.

RETURNS

  The cluster object identified by the given name or the default cluster.

DESCRIPTION

If name is not specified or is null, the default cluster will be returned.

If name is specified, and no cluster with the indicated name is found, an error
will be raised.

The options dictionary accepts the connectToPrimary option,which defaults to
true and indicates the shell to automatically connect to the primary member of
the cluster.

EXCEPTIONS

  MetadataError in the following scenarios:

   - If the Metadata is inaccessible.
   - If the Metadata update operation failed.

  ArgumentError in the following scenarios:

   - If the Cluster name is empty.
   - If the Cluster name is invalid.
   - If the Cluster does not exist.

  RuntimeError in the following scenarios:

   - If the current connection cannot be used for Group Replication.
```

21.2 Creating an InnoDB Cluster

This section explains the different ways you can create an InnoDB cluster, the requirements for server instances and the software you need to install to deploy a cluster.

21.2.1 Deployment Scenarios

InnoDB cluster supports the following deployment scenarios:

- *Production deployment:* if you want to use InnoDB cluster in a full production environment you need to configure the required number of machines and then deploy your server instances to the

machines. A production deployment enables you to exploit the high availability features of InnoDB cluster to their full potential. See Section 21.2.4, “Production Deployment of InnoDB Cluster” for instructions.

- *Sandbox deployment:* if you want to test out InnoDB cluster before committing to a full production deployment, the provided sandbox feature enables you to quickly set up a cluster on your local machine. Sandbox server instances are created with the required configuration and you can experiment with InnoDB cluster to become familiar with the technologies employed. See Section 21.2.5, “Sandbox Deployment of InnoDB Cluster” for instructions.

Important

A sandbox deployment is not suitable for use in a full production environment.

21.2.2 InnoDB Cluster Requirements

Before installing a production deployment of InnoDB cluster, ensure that the server instances you intend to use meet the following requirements.

- InnoDB cluster uses Group Replication and therefore your server instances must meet the same requirements. See Section 18.9.1, “Group Replication Requirements”. AdminAPI provides the `dba.checkInstanceConfiguration()` method to verify that an instance meets the Group Replication requirements, and the `dba.configureInstance()` method to configure an instance to meet the requirements.

Note

When using a sandbox deployment the instances are configured to meet these requirements automatically.

- Group Replication members can contain tables using a storage engine other than `InnoDB`, for example `MyISAM`. Such tables cannot be written to by Group Replication, and therefore when using InnoDB cluster. To be able to write to such tables with InnoDB cluster, convert all such tables to `InnoDB` before using the instance in a InnoDB cluster.

- The Performance Schema must be enabled on any instance which you want to use with InnoDB cluster.

- The provisioning scripts that MySQL Shell uses to configure servers for use in InnoDB cluster require access to Python version 2.7. For a sandbox deployment Python is required on the single machine used for the deployment, production deployments require Python on each server instance which should run MySQL Shell locally, see Persisting Settings.

  On Windows MySQL Shell includes Python and no user configuration is required. On Unix Python must be found as part of the shell environment. To check that your system has Python configured correctly issue:

```
$ /usr/bin/env python
```

  If a Python interpreter starts, no further action is required. If the previous command fails, create a soft link between `/usr/bin/python` and your chosen Python binary.

21.2.3 Methods of Installing

The method you use to install InnoDB cluster depends on the type of deployment you intend to use. For a sandbox deployment install the components of InnoDB cluster to a single machine. A sandbox deployment is local to a single machine, therefore the install needs to only be done once on the local machine. For a production deployment install the components to each machine that you intend to add to your cluster. A production deployment uses multiple remote host machines running MySQL server

instances, so you need to connect to each machine using a tool such as SSH or Windows remote desktop to carry out tasks such as installing components. The following methods of installing InnoDB cluster are available:

- Downloading and installing the components using the following documentation:
  - MySQL Server - see Chapter 2, *Installing and Upgrading MySQL*.
  - MySQL Shell - see Installing MySQL Shell.
  - MySQL Router - see Installing MySQL Router.
- On Windows you can use the MySQL Installer for Windows for a sandbox deployment. For details, see High Availability.

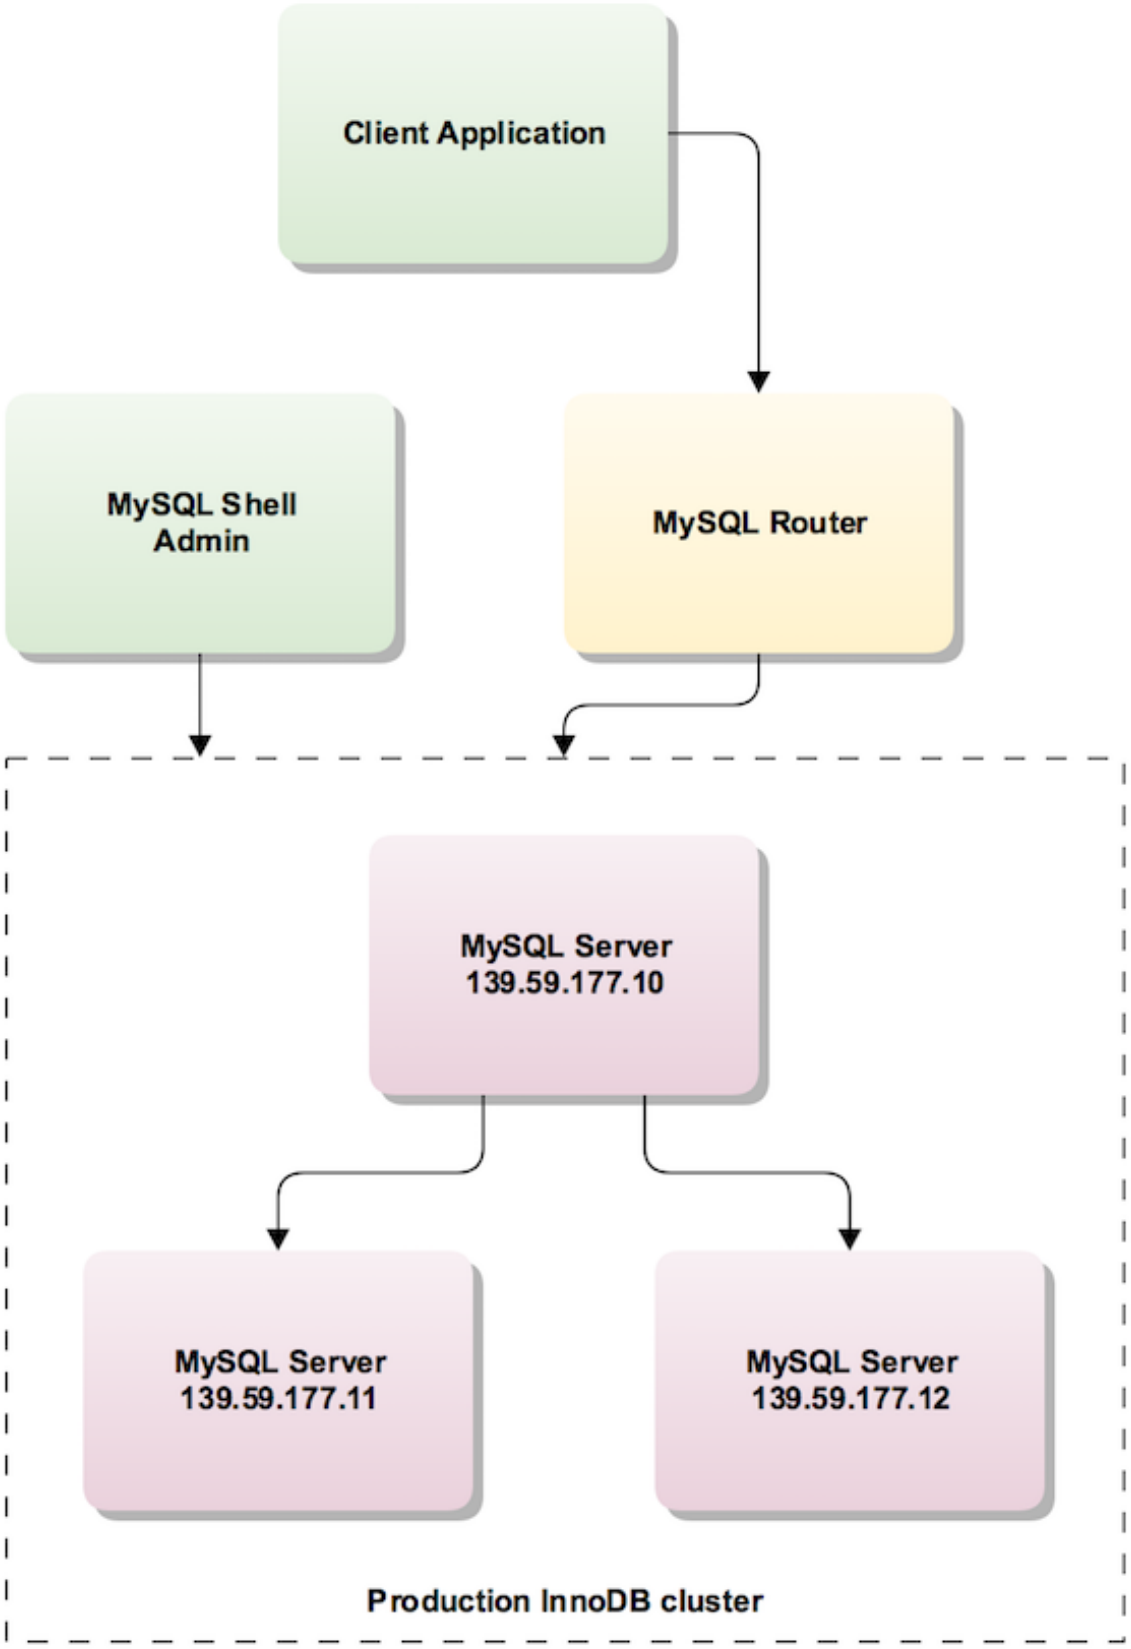
Once you have installed the software required by InnoDB cluster choose to follow either Section 21.2.5, “Sandbox Deployment of InnoDB Cluster” or Section 21.2.4, “Production Deployment of InnoDB Cluster”.

21.2.4 Production Deployment of InnoDB Cluster

When working in a production environment, the MySQL server instances which make up an InnoDB cluster run on multiple host machines as part of a network rather than on single machine as described in Section 21.2.5, “Sandbox Deployment of InnoDB Cluster”. Before proceeding with these instructions you must install the required software to each machine that you intend to add as a server instance to your cluster, see Section 21.2.3, “Methods of Installing”.

The following diagram illustrates the scenario you work with in this section:

Figure 21.2 Production Deployment



Important

Unlike a sandbox deployment, where all instances are deployed locally to one machine which AdminAPI has local file access to and can persist configuration changes, for a production deployment you must persist any configuration changes on the instance. How you do this depends on the version of MySQL running on the instance, see Persisting Settings.

To pass a server's connection information to AdminAPI use URI type strings or a data dictionary, see Section 4.2.3, “Connecting Using a URI or Key-Value Pairs”. In this documentation URI type strings are shown.

User Privileges

The user account used to administer an instance does not have to be the root account, however the user needs to be assigned full read and write privileges on the InnoDB cluster metadata tables in addition to full MySQL administrator privileges (`SUPER`, `GRANT OPTION`, `CREATE`, `DROP` and so on). The preferred method to create users to administer the cluster is using the `clusterAdmin` option with the `dba.configureInstance()`, and `Cluster.addInstance()` operations. In this procedure the user `ic` is shown in examples.

If only read operations are needed (such as for monitoring purposes), an account with more restricted privileges can be used. To give the user *`your_user`* the privileges needed to monitor InnoDB cluster issue:

```
GRANT SELECT ON mysql_innodb_cluster_metadata.* TO your_user@'%';
GRANT SELECT ON performance_schema.global_status TO your_user@'%';
GRANT SELECT ON performance_schema.replication_applier_configuration TO your_user@'%';
GRANT SELECT ON performance_schema.replication_applier_status TO your_user@'%';
GRANT SELECT ON performance_schema.replication_applier_status_by_coordinator TO your_user@'%';
GRANT SELECT ON performance_schema.replication_applier_status_by_worker TO your_user@'%';
GRANT SELECT ON performance_schema.replication_connection_configuration TO your_user@'%';
GRANT SELECT ON performance_schema.replication_connection_status TO your_user@'%';
GRANT SELECT ON performance_schema.replication_group_member_stats TO your_user@'%';
GRANT SELECT ON performance_schema.replication_group_members TO your_user@'%';
GRANT SELECT ON performance_schema.threads TO your_user@'%' WITH GRANT OPTION;
```

User Accounts Created by InnoDB Cluster

As part of using Group Replication, InnoDB cluster creates internal users which enable replication between the servers in the cluster. These users are internal to the cluster, and the user name of the generated users follows a naming scheme of `mysql_innodb_cluster_r[10_numbers]`. The hostname used for the internal users depends on whether the `ipWhitelist` option has been configured. If `ipWhitelist` is not configured, it defaults to `AUTOMATIC` and the internal users are created using both the wildcard `%` character and `localhost` for the hostname value. When `ipWhitelist` has been configured, for each address in the `ipWhitelist` list an internal user is created. For more information, see Creating a Whitelist of Servers.

Each internal user has a randomly generated password. The randomly generated users are given the following grants:

```
GRANT REPLICATION SLAVE ON *.* to internal_user;
```

The internal user accounts are created on the seed instance and then replicated to the other instances in the cluster. The internal users are:

- generated when creating a new cluster by issuing `dba.createCluster()`
- generated when adding a new instance to the cluster by issuing *`Cluster`*`.addInstance()`.

In addition, the *`Cluster`*`.rejoinInstance()` operation can also result in a new internal user being generated when the `ipWhitelist` option is used to specify a hostname. For example by issuing:

```
Cluster.rejoinInstance({ipWhitelist: "192.168.1.1/22"});
```

all previously existing internal users are removed and a new internal user is created, taking into account the `ipWhitelist` value used.

For more information on the internal users required by Group Replication, see Section 18.2.1.3, “User Credentials”.

Configuring Hostname

The production instances which make up a cluster run on separate machines, therefore each machine must have a unique host name and be able to resolve the host names of the other machines which run server instances in the cluster. If this is not the case, you can:

- configure each machine to map the IP of each other machine to a hostname. See your operating system documentation for details. This is the recommended solution.
- set up a DNS service
- configure the `report_host` variable in the MySQL configuration of each instance to a suitable externally reachable address

In this procedure the host name `ic-`*`number`* is used in examples.

To verify whether the hostname of a MySQL server is correctly configured, execute the following query to see how the instance reports its own address to other servers and try to connect to that MySQL server from other hosts using the returned address:

```
SELECT coalesce(@@report_host, @@hostname);
```

Persisting Settings

The AdminAPI commands you use to work with a cluster and it's server instances modify the configuration of the instance. Depending on the way MySQL Shell is connected to the instance and the version of MySQL installed on the instance, these configuration changes can be persisted to the instance automatically. Persisting settings to the instance ensures that configuration changes are retained after the instance restarts, for background information see `SET PERSIST`. This is essential for reliable cluster usage, for example if settings are not persisted then an instance which has been added to a cluster does not rejoin the cluster after a restart because configuration changes are lost. Persisting changes is required after the following operations:

- `dba.configureInstance()`
- `dba.createCluster()`
- *`Cluster`*`.addInstance()`
- *`Cluster`*`.removeInstance()`
- *`Cluster`*`.rejoinInstance()`

Instances which meet the following requirements support persisting configuration changes automatically:

- the instance is running MySQL version 8.0.11 or later
- `persisted_globals_load` is set to `ON`

Instances which do not meet these requirements do not support persisting configuration changes automatically, when AdminAPI operations result in changes to the instance's settings to be persisted you receive warnings such as:

```
WARNING: On instance 'localhost:3320' membership change cannot be persisted since MySQL version 5.7.21
does not support the SET PERSIST command (MySQL version >= 8.0.5 required). Please use the
<Dba>.configureLocalInstance command locally to persist the changes.
```

When AdminAPI commands are issued against the MySQL instance which MySQL Shell is currently running on, in other words the local instance, MySQL Shell persists configuration changes directly to the instance. On local instances which support persisting configuration changes automatically, configuration changes are persisted to the instance's `mysqld-auto.cnf` file and the configuration change does not require any further steps. On local instances which do not support persisting configuration changes automatically, you need to make the changes locally, see Configuring Instances with `dba.configureLocalInstance()`.

When run against a remote instance, in other words an instance other than the one which MySQL Shell is currently running on, if the instance supports persisting configuration changes automatically, the AdminAPI commands persist configuration changes to the instance's `mysql-auto.conf` option file. If a remote instance does not support persisting configuration changes automatically, the AdminAPI commands can not automatically configure the instance's option file. This means that AdminAPI commands can read information from the instance, for example to display the current configuration, but changes to the configuration cannot be persisted to the instance's option file. In this case, you need to persist the changes locally, see Configuring Instances with `dba.configureLocalInstance()`.

Verbose Logging

When working with a production deployment it can be useful to configure verbose logging for MySQL Shell, the information in the log can help you to find and resolve any issues that might occur when you are preparing server instances to work as part of InnoDB cluster. To start MySQL Shell with a verbose logging level use the `--log-level` option:

```
shell> mysqlsh --log-level=DEBUG3
```

The `DEBUG3` is recommended, see `--log-level` for more information. When `DEBUG3` is set the MySQL Shell log file contains lines such as `Debug: execute_sql( ... )` which contain the SQL queries that are executed as part of each AdminAPI call. The log file generated by MySQL Shell is located in `~/.mysqlsh/mysqlsh.log` for Unix-based systems; on Microsoft Windows systems it is located in `%APPDATA%\MySQL\mysqlsh\mysqlsh.log`. See MySQL Shell Application Log for more information.

In addition to enabling the MySQL Shell log level, you can configure the amount of output AdminAPI provides in MySQL Shell after issuing each command. To enable the amount of AdminAPI output, in MySQL Shell issue:

```
mysql-js> dba.verbose=2
```

This enables the maximum output from AdminAPI calls. The available levels of output are:

- 0 or OFF is the default. This provides minimal output and is the recommended level when not troubleshooting.
- 1 or ON adds verbose output from each call to the AdminAPI.
- 2 adds debug output to the verbose output providing full information about what each call to AdminAPI executes.

Configuring Production Instances

AdminAPI provides the `dba.configureInstance()` function that checks if an instance is suitably configured for InnoDB cluster usage, and configures the instance if it finds any settings which are not compatible with InnoDB cluster. You run the `dba.configureInstance()` command against an instance and it checks all of the settings required to enable the instance to be used for InnoDB

cluster usage. If the instance does not require configuration changes, there is no need to modify the configuration of the instance, and the `dba.configureInstance()` command output confirms that the instance is ready for InnoDB cluster usage. If any changes are required to make the instance compatible with InnoDB cluster, a report of the incompatible settings is displayed, and you can choose to let the command make the changes to the instance's option file. Depending on the way MySQL Shell is connected to the instance, and the version of MySQL running on the instance, you can make these changes permanent by persisting them to a remote instance's option file, see Persisting Settings. Instances which do not support persisting configuration changes automatically require that you configure the instance locally, see Configuring Instances with `dba.configureLocalInstance()`. Alternatively you can make the changes to the instance's option file manually, see Section 4.2.7, “Using Option Files” for more information. Regardless of the way you make the configuration changes, you might have to restart MySQL to ensure the configuration changes are detected.

The syntax of the `dba.configureInstance()` command is:

```
dba.configureInstance([instance][, options])
```

where *`instance`* is an instance definition, and *`options`* is a data dictionary with additional options to configure the operation. The command returns a descriptive text message about the operation's result.

The instance definition is the connection data for the instance. If the target instance already belongs to an InnoDB cluster an error is generated and the process fails.

The options dictionary can contain the following:

- `mycnfPath` - the path to the MySQL option file of the instance.
- `outputMycnfPath` - alternative output path to write the MySQL option file of the instance.
- `password` - the password to be used by the connection.
- `clusterAdmin` - the name of an InnoDB cluster administrator user to be created. The supported format is the standard MySQL account name format. Supports identifiers or strings for the user name and host name. By default if unquoted it assumes input is a string.
- `clusterAdminPassword` - the password for the InnoDB cluster administrator account being created using `clusterAdmin`.
- `clearReadOnly` - a boolean value used to confirm that `super_read_only` should be set to off, see Super Read-only and Instances.
- `interactive` - a boolean value used to disable the interactive wizards in the command execution, so that prompts are not provided to the user and confirmation prompts are not shown.
- `restart` - a boolean value used to indicate that a remote restart of the target instance should be performed to finalize the operation.

The connection password can be contained in the instance definition. Alternatively, it can be overwritten by specifying it using the `password` option.

Once `dba.configureInstance()` is issued against an instance, the command checks if the instance's settings are suitable for InnoDB cluster usage. A report is displayed which shows the settings required by InnoDB cluster . If the instance does not require any changes to its settings you can use it in an InnoDB cluster, and can proceed to Creating the Cluster. If the instance's settings are not valid for InnoDB cluster usage the `dba.configureInstance()` command displays the settings which require modification. Before configuring the instance you are prompted to confirm the changes shown in a table with the following information:

- `Variable` - the invalid configuration variable.
- `Current Value` - the current value for the invalid configuration variable.

- `Required Value` - the required value for the configuration variable.

How you proceed depends on whether the instance supports persisting settings, see Persisting Settings. When `dba.configureInstance()` is issued against the MySQL instance which MySQL Shell is currently running on, in other words the local instance, it attempts to automatically configure the instance. When `dba.configureInstance()` is issued against a remote instance, if the instance supports persisting configuration changes automatically, you can choose to do this. If a remote instance does not support persisting the changes to configure it for InnoDB cluster usage, you have to configure the instance locally. See Configuring Instances with `dba.configureLocalInstance()`.

In general, a restart of the instance is not required after `dba.configureInstance()` configures the option file, but for some specific settings a restart might be required. This information is shown in the report generated after issuing `dba.configureInstance()`. If the instance supports the `RESTART` statement, MySQL Shell can shutdown and then start the instance. This ensures that the changes made to the instance's option file are detected by mysqld. For more information see `RESTART`.

Note

After executing a `RESTART` statement, the current connection to the instance is lost. If auto-reconnect is enabled, the connection is reestablished after the server restarts. Otherwise, the connection must be reestablished manually.

The `dba.configureInstance()` method verifies that a suitable user is available for cluster usage, which is used for connections between members of the cluster, see User Privileges . The recommended way to add a suitable user is to use the `clusterAdmin` and `clusterAdminPassword` options, which enable you to configure the cluster user and password when calling the function. For example:

```
mysql-js> dba.configureInstance('ic@ic-1:3306', \
{clusterAdmin: "'icadmin'@'ic-1'%", clusterAdminPassword: 'password'});
```

This user is granted the privileges to be able to administer the cluster. The format of the user names accepted follows the standard MySQL account name format, see Section 6.2.4, “Specifying Account Names”.

If you do not specify a user to administer the cluster, in interactive mode a wizard enables you to choose one of the following options:

- enable remote connections for the root user
- create a new user, the equivalent of specifying the `clusterAdmin` and `clusterAdminPassword` options
- no automatic configuration, in which case you need to manually create the user

The following example demonstrates the option to create a new user for cluster usage.

```
mysql-js> dba.configureLocalInstance('root@localhost:3306')

Please provide the password for 'root@localhost:3306':

Please specify the path to the MySQL configuration file: /etc/mysql/mysql.conf.d/mysqld.cnf
Validating instance...

The configuration has been updated but it is required to restart the server.
{

      "current": "OFF",
      "option": "transaction_write_set_extraction",
      "required": "XXHASH64"
    }
  ],
  "errors": [],
  "restart_required": true,
  "status": "error"
}
mysql-js>
```

Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See Super Read-only and Instances for more information.

Creating the Cluster

Once you have prepared your instances, use the `dba.createCluster()` function to create the cluster. The machine which you are running MySQL Shell on is used as the seed instance for the cluster. The seed instance is replicated to the other instances which you add to the cluster, making them replicas of the seed instance.

MySQL Shell must be connected to an instance before you can create a cluster because when you issue `dba.createCluster(name)` MySQL Shell creates a MySQL protocol session to the server instance connected to the MySQL Shell's current global session. Use the `dba.createCluster(name)` function to create the cluster and assign the returned cluster to a variable called `cluster`:

```
mysql-js> var cluster = dba.createCluster('testCluster')

Validating instance at ic@ic-1:3306...

This instance reports its own address as ic-1
```

```
Instance configuration is suitable.
Creating InnoDB cluster 'testCluster' on 'ic@ic-1:3306'...

Adding Seed Instance...
Cluster successfully created. Use Cluster.addInstance() to add MySQL instances.
At least 3 instances are needed for the cluster to be able to withstand up to
one server failure.
```

The returned Cluster object uses a new session, independent from the MySQL Shell's main session. This ensures that if you change the MySQL Shell global session, the Cluster object maintains its session to the instance.

Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See Super Read-only and Instances for more information.

Note

If you encounter an error related to metadata being inaccessible you might have the loopback network interface configured. For correct InnoDB cluster usage disable the loopback interface.

To check the cluster has been created, use the cluster instance's `status()` function. See Checking a cluster's Status with *`Cluster`*`.status()`.

Tip

Once server instances belong to a cluster it is important to only administer them using MySQL Shell and AdminAPI. Attempting to manually change the configuration of Group Replication on an instance once it has been added to a cluster is not supported. Similarly, modifying server variables critical to InnoDB cluster, such as `server_uuid` after an instance is configured using AdminAPI is not supported.

When you create a cluster using MySQL Shell 8.0.14 and later, you can set the timeout before instances are expelled from the cluster, for example when they become unreachable. Pass the `expelTimeout` option to the `dba.createCluster()` operation, which configures the `group_replication_member_expel_timeout` variable on the seed instance. The `expelTimeout` option can take an integer value in the range of 0 to 3600. All instances running MySQL server 8.0.13 and later which are added to a cluster with `expelTimeout` configured are automatically configured to have the same `expelTimeout` value as configured on the seed instance.

For information on the other options which you can pass to `dba.createCluster()`, see Section 21.4, “Working with InnoDB Cluster”.

Adding Instances to a Cluster

Use the `cluster.addInstance(`*`instance`*`)` function to add more instances to the cluster, where *`instance`* is connection information to a configured instance, see Configuring Production Instances. You need a minimum of three instances in the cluster to make it tolerant to the failure of one instance. Adding further instances increases the tolerance to failure of an instance. To add an instance to the cluster issue:

```
mysql-js> cluster.addInstance('ic@ic-2:3306')
A new instance will be added to the InnoDB cluster. Depending on the amount of
data on the cluster this might take from a few seconds to several hours.

Please provide the password for 'ic@ic-2:3306': ********
Adding instance to the cluster ...
```

```
Validating instance at ic-2:3306...

This instance reports its own address as ic-2

Instance configuration is suitable.

The instance 'ic@ic-2:3306' was successfully added to the cluster.
```

To verify the instance has been added, use the cluster instance's `status()` function. For example this is the status output of a sandbox cluster after adding a second instance:

```
mysql-js> cluster.status()
{
    "clusterName": "testCluster",
    "defaultReplicaSet": {
        "name": "default",
        "primary": "localhost:3310",
        "ssl": "REQUIRED",
        "status": "OK_NO_TOLERANCE",
        "statusText": "Cluster is NOT tolerant to any failures.",
        "topology": {
            "localhost:3310": {
                "address": "localhost:3310",
                "mode": "R/W",
                "readReplicas": {},
                "role": "HA",
                "status": "ONLINE"
            },
            "localhost:3320": {
                "address": "localhost:3320",
                "mode": "R/O",
                "readReplicas": {},
                "role": "HA",
                "status": "ONLINE"
            }
        }
    },
    "groupInformationSourceMember": "mysql://root@localhost:3310"
}
```

How you proceed depends on whether the instance is local or remote to the instance MySQL Shell is running on, and whether the instance supports persisting configuration changes automatically, see Persisting Settings. If the instance supports persisting configuration changes automatically, you do not need to persist the settings manually and can either add more instances or continue to the next step. If the instance does not support persisting configuration changes automatically, you have to configure the instance locally. See Configuring Instances with `dba.configureLocalInstance()`. This is essential to ensure that instances rejoin the cluster in the event of leaving the cluster.

Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See Super Read-only and Instances for more information.

Once you have your cluster deployed you can configure MySQL Router to provide high availability, see Section 21.3, “Using MySQL Router with InnoDB Cluster”.

21.2.5 Sandbox Deployment of InnoDB Cluster

This section explains how to set up a sandbox InnoDB cluster deployment. You create and administer your InnoDB clusters using MySQL Shell with the included AdminAPI. This section assumes familiarity with MySQL Shell, see MySQL Shell 8.0 (part of MySQL 8.0) for further information.

Initially deploying and using local sandbox instances of MySQL is a good way to start your exploration of InnoDB cluster. You can fully test out InnoDB cluster locally, prior to deployment on your production

servers. MySQL Shell has built-in functionality for creating sandbox instances that are correctly configured to work with Group Replication in a locally deployed scenario.

Important

Sandbox instances are only suitable for deploying and running on your local machine for testing purposes. In a production environment the MySQL Server instances are deployed to various host machines on the network. See Section 21.2.4, “Production Deployment of InnoDB Cluster” for more information.

This tutorial shows how to use MySQL Shell to create an InnoDB cluster consisting of three MySQL server instances.

- Deploying Sandbox Instances
- Creating the Sandbox InnoDB Cluster
- Adding Instances to an InnoDB Cluster
- Persisting the Sandbox Configuration

Deploying Sandbox Instances

MySQL Shell includes the AdminAPI that adds the `dba` global variable, which provides functions for administration of sandbox instances. In this example setup, you create three sandbox instances using `dba.deploySandboxInstance()`.

Start MySQL Shell from a command prompt by issuing the command:

```
shell> mysqlsh
```

MySQL Shell provides two scripting language modes, JavaScript and Python, in addition to a native SQL mode. Throughout this guide MySQL Shell is used primarily in JavaScript mode . When MySQL Shell starts it is in JavaScript mode by default. Switch modes by issuing `\js` for JavaScript mode, `\py` for Python mode, and `\sql` for SQL mode. Ensure you are in JavaScript mode by issuing the `\js` command, then execute:

```
mysql-js> dba.deploySandboxInstance(3310)
```

Note

Terminating commands with a semi-colon is not required in JavaScript and Python modes.

The argument passed to `deploySandboxInstance()` is the TCP port number where the MySQL Server instance listens for connections. By default the sandbox is created in a directory named `$HOME/mysql-sandboxes/`*`port`* on Unix systems. For Microsoft Windows systems the directory is `%userprofile%\MySQL\mysql-sandboxes\`*`port`*.

The root user's password for the instance is prompted for.

Important

Each instance has its own password. Defining the same password for all sandboxes in this tutorial makes it easier, but remember to use different passwords for each instance in production deployments.

To deploy further sandbox server instances, repeat the steps followed for the sandbox instance at port 3310, choosing different port numbers. For each additional sandbox instance issue:

```
mysql-js> dba.deploySandboxInstance(port_number)
```

To follow this tutorial, use port numbers 3310, 3320 and 3330 for the three sandbox server instances. Issue:

```
mysql-js> dba.deploySandboxInstance(3320)
mysql-js> dba.deploySandboxInstance(3330)
```

Creating the Sandbox InnoDB Cluster

The next step is to create the InnoDB cluster while connected to the seed MySQL Server instance. The seed instance contains the data that you want to replicate to the other instances. In this example the sandbox instances are blank, therefore we can choose any instance.

Connect MySQL Shell to the seed instance, in this case the one at port 3310:

```
mysql-js> \connect root@localhost:3310
```

The `\connect` MySQL Shell command is a shortcut for the `shell.connect()` method:

```
mysql-js> shell.connect('user@localhost:3310')
```

Once you have connected, AdminAPI can write to the local instance's option file. This is different to working with a production deployment, where you would need to persist settings to the instance's option file.

Use the `dba.createCluster()` method to create the InnoDB cluster with the currently connected instance as the seed:

```
mysql-js> var cluster = dba.createCluster('testCluster')
```

The `createCluster()` method deploys the InnoDB cluster metadata to the selected instance, and adds the instance you are currently connected to as the seed instance. The `createCluster()` method returns the created cluster, in the example above this is assigned to the `cluster` variable. The parameter passed to the `createCluster()` method is a symbolic name given to this InnoDB cluster, in this case `testCluster`.

Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See Super Read-only and Instances for more information.

Adding Instances to an InnoDB Cluster

The next step is to add more instances to the InnoDB cluster. Any transactions that were executed by the seed instance are re-executed by each secondary instance as it is added. This tutorial uses the sandbox instances that were created earlier at ports 3320 and 3330.

The seed instance in this example was recently created, so it is nearly empty. Therefore, there is little data that needs to be replicated from the seed instance to the secondary instances. In a production environment, where you have an existing database on the seed instance, you could use a tool such as MySQL Enterprise Backup to ensure that the secondaries have matching data before replication starts. This avoids the possibility of lengthy delays while data replicates from the primary to the secondaries. See Section 18.4.7, “Using MySQL Enterprise Backup with Group Replication”.

Add the second instance to the InnoDB cluster:

```
mysql-js> cluster.addInstance('root@localhost:3320')
```

The root user's password is prompted for.

Add the third instance:

```
mysql-js> cluster.addInstance('root@localhost:3330')
```

The root user's password is prompted for.

At this point you have created a cluster with three instances: a primary, and two secondaries.

Tip

You can only specify `localhost` in `addInstance()` if the instance is a sandbox instance. This also applies to the implicit `addInstance()` after issuing `createCluster()`.

Persisting the Sandbox Configuration

Once the sandbox instances have been added to the cluster, the configuration required for InnoDB cluster must be persisted to each of the instance's option files. How you proceed depends on whether the instance supports persisting configuration changes automatically, see Persisting Settings. When the MySQL instance which you are using supports persisting configuration changes automatically, adding the instance automatically configures the instance. When the MySQL instance which you are using does not support persisting configuration changes automatically, you have to configure the instance locally. See Configuring Instances with `dba.configureLocalInstance()`.

To check the cluster has been created, use the cluster instance's `status()` function. See Checking a cluster's Status with *`Cluster`*`.status()`.

Once you have your cluster deployed you can configure MySQL Router to provide high availability, see Section 21.3, “Using MySQL Router with InnoDB Cluster”.

21.2.6 Adopting a Group Replication Deployment

If you have an existing deployment of Group Replication and you want to use it to create a cluster, pass the `adoptFromGR` option to the `dba.createCluster()` function. The created InnoDB cluster matches whether the replication group is running as single-primary or multi-primary.

To adopt an existing Group Replication group, connect to a group member using MySQL Shell. In the following example a single-primary group is adopted. We connect to `gr-member-2`, a secondary instance, while `gr-member-1` is functioning as the group's primary. Create a cluster using `dba.createCluster()`, passing in the `adoptFromGR` option. For example:

```
mysql-js> var cluster = dba.createCluster('prodCluster', {adoptFromGR: true});

A new InnoDB cluster will be created on instance 'root@gr-member-2:3306'.

Creating InnoDB cluster 'prodCluster' on 'root@gr-member-2:3306'...
Adding Seed Instance...

Cluster successfully created. Use cluster.addInstance() to add MySQL instances.
At least 3 instances are needed for the cluster to be able to withstand up to
one server failure.
```

Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See Super Read-only and Instances for more information.

The new cluster matches the mode of the group. If the adopted group was running in single-primary mode then a single-primary cluster is created. If the adopted group was running in multi-primary mode then a multi-primary cluster is created.

21.3 Using MySQL Router with InnoDB Cluster

This section describes how to use MySQL Router with InnoDB cluster to achieve high availability. Regardless of whether you have deployed a sandbox or production cluster, MySQL Router can configure itself based on the InnoDB cluster's metadata using the `--bootstrap` option. This configures MySQL Router automatically to route connections to the cluster's server instances. Client applications connect to the ports MySQL Router provides, without any need to be aware of the InnoDB cluster topology. In the event of a unexpected failure, the InnoDB cluster adjusts itself automatically and MySQL Router detects the change. This removes the need for your client application to handle failover. For more information, see Routing for MySQL InnoDB cluster.

Note

Do not attempt to configure MySQL Router manually to redirect to the ports of an InnoDB cluster. Always use the `--bootstrap` option as this ensures that MySQL Router takes its configuration from the InnoDB cluster's metadata. See Cluster Metadata and State.

The recommended deployment of MySQL Router is on the same host as the application. When using a sandbox deployment, everything is running on a single host, therefore you deploy MySQL Router to the same host. When using a production deployment, we recommend deploying one MySQL Router instance to each machine used to host one of your client applications. It is also possible to deploy MySQL Router to a common machine through which your application instances connect.

Assuming MySQL Router is already installed (see Installing MySQL Router), use the `--bootstrap` option to provide the location of a server instance that belongs to the InnoDB cluster. MySQL Router uses the included metadata cache plugin to retrieve the InnoDB cluster's metadata, consisting of a list of server instance addresses which make up the InnoDB cluster and their role in the cluster. You pass the URI type string of the server that MySQL Router should retrieve the InnoDB cluster metadata from. For example:

```
shell> mysqlrouter --bootstrap ic@ic-1:3306 --user=mysqlrouter
```

You are prompted for the instance password and encryption key for MySQL Router to use. This encryption key is used to encrypt the instance password used by MySQL Router to connect to the cluster. The ports you can use to connect to the InnoDB cluster are also displayed. The MySQL Router bootstrap process creates a `mysqlrouter.conf` file, with the settings based on the cluster metadata retrieved from the address passed to the `--bootstrap` option, in the above example `ic@ic-1:3306`. Based on the InnoDB cluster metadata retrieved, MySQL Router automatically configures the `mysqlrouter.conf` file, including a `metadata_cache` section with `bootstrap_server_addresses` containing the addresses for all server instances in the cluster. For example:

```
[metadata_cache:prodCluster]
router_id=1
bootstrap_server_addresses=mysql://ic@ic-1:3306,mysql://ic@ic-2:3306,mysql://ic@ic-3:3306
user=mysql_router1_jy95yozko3k2
metadata_cluster=prodCluster
ttl=300
```

Tip

When you change the topology of a cluster by adding another server instance after you have bootstrapped MySQL Router, you need to update `bootstrap_server_addresses` based on the updated metadata. Either

> restart MySQL Router using the `--bootstrap` option, or manually edit the `bootstrap_server_addresses` section of the `mysqlrouter.conf` file and restart MySQL Router.

The generated MySQL Router configuration creates TCP ports which you use to connect to the cluster. Ports for communicating with the cluster using both Classic MySQL protocol and X Protocol are created. To use X Protocol the server instances must have X Plugin installed and configured. For a sandbox deployment, instances have X Plugin set up automatically. For a production deployment, if you want to use X Protocol you need to install and configure X Plugin on each instance, see Installing MySQL Shell. The default available TCP ports are:

- `6446` - for Classic MySQL protocol read-write sessions, which MySQL Router redirects incoming connections to primary server instances.
- `6447` - for Classic MySQL protocol read-only sessions, which MySQL Router redirects incoming connections to one of the secondary server instances.
- `64460` - for X Protocol read-write sessions, which MySQL Router redirects incoming connections to primary server instances.
- `64470` - for X Protocol read-only sessions, which MySQL Router redirects incoming connections to one of the secondary server instances.

Depending on your MySQL Router configuration the port numbers might be different to the above. For example if you use the `--conf-base-port` option, or the `group_replication_single_primary_mode` variable. The exact ports are listed when you start MySQL Router.

The way incoming connections are redirected depends on the type of cluster being used. When using a single-primary cluster, by default MySQL Router publishes a X Protocol and a classic protocol port, which clients connect to for read-write sessions and which are redirected to the cluster's single primary. With a multi-primary cluster read-write sessions are redirected to one of the primary instances in a round-robin fashion. For example, this means that the first connection to port 6446 would be redirected to the ic-1 instance, the second connection to port 6446 would be redirected to the ic-2 instance, and so on. For incoming read-only connections MySQL Router redirects connections to one of the secondary instances, also in a round-robin fashion. To modify this behavior see the `routing_strategy` option.

Once bootstrapped and configured, start MySQL Router. If you used a system wide install with the `--bootstrap` option then issue:

```
shell> mysqlrouter &
```

If you installed MySQL Router to a directory using the `--directory` option, use the `start.sh` script found in the directory you installed to. Alternatively set up a service to start MySQL Router automatically when the system boots, see Starting MySQL Router. You can now connect a MySQL client, such as MySQL Shell to one of the incoming MySQL Router ports as described above and see how the client gets transparently connected to one of the InnoDB cluster instances.

```
shell> mysqlsh --uri root@localhost:6442
```

To verify which instance you are actually connected to, simply issue an SQL query against the `port` status variable.

```
mysql-js> \sql
Switching to SQL mode... Commands end with ;
mysql-sql> select @@port;
+--------+
| @@port |
```

```
+--------+
|   3310 |
+--------+
```

Testing High Availability

To test if high availability works, simulate an unexpected halt by killing an instance. The cluster detects the fact that the instance left the cluster and reconfigures itself. Exactly how the cluster reconfigures itself depends on whether you are using a single-primary or multi-primary cluster, and the role the instance serves within the cluster.

In single-primary mode:

- If the current primary leaves the cluster, one of the secondary instances is elected as the new primary, with instances prioritized by the lowest `server_uuid`. MySQL Router redirects read-write connections to the newly elected primary.
- If a current secondary leaves the cluster, MySQL Router stops redirecting read-only connections to the instance.

For more information see Section 18.4.1.1, “Single-Primary Mode”.

In multi-primary mode:

- If a current "R/W" instance leaves the cluster, MySQL Router redirects read-write connections to other primaries. If the instance which left was the last primary in the cluster then the cluster is completely gone and you cannot connect to any MySQL Router port.

For more information see Section 18.4.1.2, “Multi-Primary Mode”.

There are various ways to simulate an instance leaving a cluster, for example you can forcibly stop the MySQL server on an instance, or use the AdminAPI `dba.killSandboxInstance()` if testing a sandbox deployment. In this example assume there is a single-primary sandbox cluster deployment with three server instances and the instance listening at port 3310 is the current primary. Simulate the instance leaving the cluster unexpectedly:

```
mysql-js> dba.killSandboxInstance(3310)
```

The cluster detects the change and elects a new primary automatically. Assuming your session is connected to port 6446, the default read-write classic MySQL protocol port, MySQL Router should detect the change to the cluster's topology and redirect your session to the newly elected primary. To verify this, switch to SQL mode in MySQL Shell using the `\sql` command and select the instance's `port` variable to check which instance your session has been redirected to. Notice that the first `SELECT` statement fails as the connection to the original primary was lost. This means the current session has been closed, MySQL Shell automatically reconnects for you and when you issue the command again the new port is confirmed.

```
mysql-js> \sql
Switching to SQL mode... Commands end with ;
mysql-sql> SELECT @@port;
ERROR: 2013 (HY000): Lost connection to MySQL server during query
The global session got disconnected.
Attempting to reconnect to 'root@localhost:6446'...
The global session was successfully reconnected.
mysql-sql> SELECT @@port;
+--------+
| @@port |
+--------+
|   3330 |
+--------+
1 row in set (0.00 sec)
```

In this example, the instance at port 3330 has been elected as the new primary. This shows that the InnoDB cluster provided us with automatic failover, that MySQL Router has automatically reconnected us to the new primary instance, and that we have high availability.

MySQL Router and Metadata Servers

When MySQL Router is bootstrapped against a cluster, it records the server instance's addresses in its configuration file. If any additional instances are added to the cluster after bootstrapping the MySQL Router, they are not automatically detected and therefore are *not* used for connection routing.

To ensure that newly added instances are routed to correctly you must bootstrap MySQL Router against the cluster to read the updated metadata. This means that you must restart MySQL Router and include the `--bootstrap` option.

21.4 Working with InnoDB Cluster

This section explains how to work with InnoDB cluster, and how to handle common administration tasks.

- Using `dba.checkInstanceConfiguration()`
- Configuring Instances with `dba.configureLocalInstance()`
- Retrieving an InnoDB cluster with `dba.getCluster()`
- Checking a cluster's Status with *`Cluster`*`.status()`
- Using `cluster.describe()`
- Super Read-only and Instances
- Managing Sandbox Instances
- Removing Instances from the InnoDB Cluster
- Customizing InnoDB clusters
- Rejoining a Cluster
- Restoring a Cluster from Quorum Loss
- Rebooting a Cluster from a Major Outage
- Rescanning a Cluster
- Checking Instance State
- Dissolving an InnoDB Cluster
- Securing your Cluster
- Creating a Whitelist of Servers
- Scripting AdminAPI
- Configuring the Election Process
- Configuring Failover Consistency
- Changing a Cluster's Topology
- Setting Options for InnoDB cluster
- InnoDB cluster and Auto-increment

Using dba.checkInstanceConfiguration()

Before creating a production deployment from server instances you need to check that MySQL on each instance is correctly configured. In addition to dba.configureInstance(), which checks the configuration as part of configuring an instance, you can use the dba.checkInstanceConfiguration() function. This ensures that the instance satisfies the Section 21.2.2, “InnoDB Cluster Requirements” without changing any configuration on the instance. This does not check any data that is on the instance, see Checking Instance State for more information. The following demonstrates issuing this in a running MySQL Shell:

```
mysql-js> dba.checkInstanceConfiguration('ic@ic-1:3306')
Please provide the password for 'ic@ic-1:3306': ***
Validating MySQL instance at ic-1:3306 for use in an InnoDB cluster...

This instance reports its own address as ic-1
Clients and other cluster members will communicate with it through this address by default.
If this is not correct, the report_host MySQL system variable should be changed.

Checking whether existing tables comply with Group Replication requirements...
No incompatible tables detected

Checking instance configuration...

Some configuration options need to be fixed:
+--------------------------+---------------+----------------+-----------------------------------------
| Variable                 | Current Value | Required Value | Note
+--------------------------+---------------+----------------+-----------------------------------------
| binlog_checksum          | CRC32         | NONE           | Update the server variable
| enforce_gtid_consistency | OFF           | ON             | Update read-only variable and restart the ser
| gtid_mode                | OFF           | ON             | Update read-only variable and restart the ser
| server_id                | 1             |                | Update read-only variable and restart the ser
+--------------------------+---------------+----------------+-----------------------------------------

Please use the dba.configureInstance() command to repair these issues.

{
    "config_errors": [
        {
            "action": "server_update",
            "current": "CRC32",
            "option": "binlog_checksum",
            "required": "NONE"
        },
        {
            "action": "restart",
            "current": "OFF",
            "option": "enforce_gtid_consistency",
            "required": "ON"
        },
        {
            "action": "restart",
            "current": "OFF",
            "option": "gtid_mode",
            "required": "ON"
        },
        {
            "action": "restart",
            "current": "1",
            "option": "server_id",
            "required": ""
        }
    ],
    "status": "error"
}
```

Repeat this process for each server instance that you plan to use as part of your cluster. The report generated after running dba.checkInstanceConfiguration() provides information about any configuration changes required before you can proceed. The action field in the config_error

section of the report tells you whether MySQL on the instance requires a restart to detect any change made to the configuration file.

Configuring Instances with dba.configureLocalInstance()

Instances which do not support persisting configuration changes automatically (see Persisting Settings) require you to connect to the server, run MySQL Shell, connect to the instance locally and issue dba.configureLocalInstance(). This enables MySQL Shell to modify the instance's option file after running the following commands against a remote instance:

- dba.configureInstance()
- dba.createCluster()
- *Cluster*.addInstance()
- *Cluster*.removeInstance()
- *Cluster*.rejoinInstance()

Important

Failing to persist configuration changes to an instance's option file can result in the instance not rejoining the cluster after the next restart.

The recommended method is to log in to the remote machine, for example using SSH, run MySQL Shell as the root user and then connect to the local MySQL server. For example, use the --uri option to connect to the local *instance*:

```
shell> sudo -i mysqlsh --uri=instance
```

Alternatively use the \connect command to log in to the local instance. Then issue dba.configureInstance(*instance*), where *instance* is the connection information to the local instance, to persist any changes made to the local instance's option file.

```
mysql-js> dba.configureLocalInstance('ic@ic-2:3306')
```

Repeat this process for each instance in the cluster which does not support persisting configuration changes automatically. For example if you add 2 instances to a cluster which do not support persisting configuration changes automatically, you must connect to each server and persist the configuration changes required for InnoDB cluster before the instance restarts. Similarly if you modify the cluster structure, for example changing the number of instances, you need to repeat this process for each server instance to update the InnoDB cluster metadata accordingly for each instance in the cluster.

Retrieving an InnoDB cluster with dba.getCluster()

When you create a cluster using dba.createCluster(), the operation returns a Cluster object which can be assigned to a variable. You use this object to work with the cluster, for example to add instances or check the cluster's status. If you want to retrieve a cluster again at a later date, for example after restarting MySQL Shell, use the dba.getCluster([*name*],[*options*]) function. For example:

```
mysql-js> var cluster1 = dba.getCluster()
```

If you do not specify a cluster *name* then the default cluster is returned. By default MySQL Shell attempts to connect to the primary instance of the cluster when you use dba.getCluster(). Set the connectToPrimary option to configure this behavior. If connectToPrimary is true and the

active global MySQL Shell session is not to a primary instance, the cluster is queried for the primary member and the cluster object connects to it. If there is no quorum in the cluster, the operation fails. If `connectToPrimary` is `false`, the cluster object uses the active session, in other words the same instance as the MySQL Shell's current global session. If `connectToPrimary` is not specified, MySQL Shell treats `connectToPrimary` as `true`, and falls back to `connectToPrimary` being `false`.

To force connecting to a secondary when getting a cluster, establish a connection to the secondary member of the cluster and use the `connectToPrimary` option by issuing:

```
mysql-js> shell.connect(secondary_member)
mysql-js> var cluster1 = dba.getCluster(testCluster, {connectToPrimary:false})
```

Tip

Remember that secondary instances have `super_read_only=ON`, so you cannot write changes to them.

Checking a cluster's Status with `Cluster.status()`

Cluster objects provide the `status()` method that enables you to check how a cluster is running. Before you can check the status of the InnoDB cluster, you need to get a reference to the InnoDB cluster object by connecting to any of its instances. However, if you want to make changes to the configuration of the cluster, you must connect to a "R/W" instance. Issuing `status()` retrieves the status of the cluster based on the view of the cluster which the server instance you are connected to is aware of and outputs a status report.

Important

The instance's state in the cluster directly influences the information provided in the status report. Therefore ensure the instance you are connected to has a status of `ONLINE`.

For information about how the InnoDB cluster is running, use the cluster's `status()` method:

```
mysql-js> var cluster = dba.getCluster()
mysql-js> cluster.status()
{
    "clusterName": "testcluster",
    "defaultReplicaSet": {
        "name": "default",
        "primary": "ic-1:3306",
        "ssl": "REQUIRED",
        "status": "OK",
        "statusText": "Cluster is ONLINE and can tolerate up to ONE failure.",
        "topology": {
            "ic-1:3306": {
                "address": "ic-1:3306",
                "mode": "R/W",
                "readReplicas": {},
                "role": "HA",
                "status": "ONLINE"
            },
            "ic-2:3306": {
                "address": "ic-2:3306",
                "mode": "R/O",
                "readReplicas": {},
                "role": "HA",
                "status": "ONLINE"
            },
            "ic-3:3306": {
                "address": "ic-3:3306",
                "mode": "R/O",
                "readReplicas": {},
                "role": "HA",
```

```
                "status": "ONLINE"
            }
        }
    },
    "groupInformationSourceMember": "mysql://ic@ic-1:3306"
}
```

The output of `Cluster.status()` provides the following information:

- `clusterName`: name assigned to this cluster during `dba.createCluster()`.
- `defaultReplicaSet`: the server instances which belong to an InnoDB cluster and contain the data set.
- `primary`: displayed when the cluster is operating in single-primary mode only. Shows the address of the current primary instance. If this field is not displayed, the cluster is operating in multi-primary mode.
- `ssl`: whether secure connections are used by the cluster or not. Shows values of `REQUIRED` or `DISABLED`, depending on how the `memberSslMode` option was configured during either `createCluster()` or `addInstance()`. The value returned by this parameter corresponds to the value of the `group_replication_ssl_mode` server variable on the instance. See Securing your Cluster.
- `status`: The status of this element of the cluster. For the overall cluster this describes the high availability provided by this cluster. The status is one of the following:
  - `ONLINE`: The instance is online and participating in the cluster.
  - `OFFLINE`: The instance has lost connection to the other instances.
  - `RECOVERING`: The instance is attempting to synchronize with the cluster by retrieving transactions it needs before it can become an `ONLINE` member.
  - `UNREACHABLE`: The instance has lost communication with the cluster.
  - `ERROR`: The instance has encountered an error during the recovery phase or while applying a transaction.

    Important

    Once an instance enters `ERROR` state, the `super_read_only` option is set to `ON`. To leave the `ERROR` state you must manually configure the instance with `super_read_only=OFF`.
  - `(MISSING)`: The state of an instance which is part of the configured cluster, but is currently unavailable.

    Note

    The `MISSING` state is specific to InnoDB cluster, it is not a state generated by Group Replication. MySQL Shell uses this state to indicate instances that are registered in the metadata, but cannot be found in the live cluster view.
- `topology`: The instances which have been added to the cluster.
- `Host name of instance`: The host name of an instance, for example localhost:3310.
- `role`: what function this instance provides in the cluster. Currently only HA, for high availability.
- `mode`: whether the server is read-write ("R/W") or read-only ("R/O"). The mode indicates either `R/W` (read and writable) or `R/O` (read only). In single-primary mode, only the one instance marked

"R/W" can execute transactions that update the database, so it is the primary. If that instance becomes unreachable for any reason (like an unexpected halt), one of the remaining "R/O" instances automatically takes over its place and becomes the new "R/W" primary. In multi-primary mode, all instances are marked as "R/W" and there is no single elected primary.

- groupInformationSourceMember: the internal connection used to get information about the cluster, shown as a URI type string. Usually the connection initially used to create the cluster.

The output of the *Cluster*.status() operation can be extended to enable you to display information about the underlying Group Replication group used by the cluster. To see information about the groupName and memberId, the communication protocol in use by the group, and general statistics about the number of transactions checked, proposed, and rejected by instances issue:

```
Cluster.status({extended:true})
```

To see information about recovery and regular transaction I/O, applier worker thread statistics and any lags; applier coordinator statistics, if parallel apply is enabled; error, and other information from I/O and applier threads issue

```
Cluster.status({queryMembers:true})
```

When queryMembers is set to true, a connection to each instance in the cluster is opened so that additional instance specific statistics can be queried. The exact statistics that are included in the output depend on the state and configuration of the instance and the server version. This information matches that shown in the replication_group_member_stats table, see the descriptions of the matching columns. Instances which are ONLINE have a transactions object included in the output. Instances which are RECOVERING have a recovery object included in the output. In either case, the objects can contain the following:

- appliedCount: see COUNT_TRANSACTIONS_REMOTE_APPLIED
- checkedCount: see COUNT_TRANSACTIONS_CHECKED
- committedAllMembers: see TRANSACTIONS_COMMITTED_ALL_MEMBERS
- conflictsDetectedCount: see COUNT_CONFLICTS_DETECTED
- inApplierQueueCount: see COUNT_TRANSACTIONS_REMOTE_IN_APPLIER_QUEUE
- inQueueCount: see COUNT_TRANSACTIONS_IN_QUEUE
- lastConflictFree: see LAST_CONFLICT_FREE_TRANSACTION
- proposedCount: see COUNT_TRANSACTIONS_LOCAL_PROPOSED
- rollbackCount: see COUNT_TRANSACTIONS_LOCAL_ROLLBACK

The connection section shows information from the replication_connection_status table.

The currentlyQueueing section has information about the transactions currently queued:

- immediateCommitTimestamp: see QUEUEING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP
- immediateCommitToNowTime: see QUEUEING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP minus NOW()
- originalCommitTimestamp: see QUEUEING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP
- originalCommitToNowTime: see QUEUEING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP minus NOW()
- startTimestamp: see QUEUEING_TRANSACTION_START_QUEUE_TIMESTAMP

- transaction: see QUEUEING_TRANSACTION
- lastHeartbeatTimestamp: see LAST_HEARTBEAT_TIMESTAMP

The lastQueued section has information about the most recently queued transaction:

- endTimestamp: see LAST_QUEUED_TRANSACTION_END_QUEUE_TIMESTAMP
- immediateCommitTimestamp: see LAST_QUEUED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP
- immediateCommitToEndTime: LAST_QUEUED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP minus NOW()
- originalCommitTimestamp: see LAST_QUEUED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP
- originalCommitToEndTime: LAST_QUEUED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP minus NOW()
- queueTime: LAST_QUEUED_TRANSACTION_END_QUEUE_TIMESTAMP minus LAST_QUEUED_TRANSACTION_START_QUEUE_TIMESTAMP
- startTimestamp: see LAST_QUEUED_TRANSACTION_START_QUEUE_TIMESTAMP
- transaction: see LAST_QUEUED_TRANSACTION
- receivedHeartbeats: see COUNT_RECEIVED_HEARTBEATS
- receivedTransactionSet: see RECEIVED_TRANSACTION_SET
- threadId: see THREAD_ID

Instances which are using a multithreaded slave have a workers section which contains information about the worker threads, and matches the information shown by the replication_applier_status_by_worker table.

The lastApplied section shows the following information about the last transaction applied by the worker:

- applyTime: see LAST_APPLIED_TRANSACTION_END_APPLY_TIMESTAMP minus LAST_APPLIED_TRANSACTION_START_APPLY_TIMESTAMP
- endTimestamp: see LAST_APPLIED_TRANSACTION_END_APPLY_TIMESTAMP
- immediateCommitTimestamp: see LAST_APPLIED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP
- immediateCommitToEndTime: see LAST_APPLIED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP minus NOW()
- originalCommitTimestamp: see LAST_APPLIED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP
- originalCommitToEndTime: see LAST_APPLIED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP minus NOW()
- startTimestamp: see LAST_APPLIED_TRANSACTION_START_APPLY_TIMESTAMP
- transaction: see LAST_APPLIED_TRANSACTION

The currentlyApplying section shows the following information about the transaction currently being applied by the worker:

- immediateCommitTimestamp: see APPLYING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP
- immediateCommitToNowTime: see APPLYING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP minus NOW()
- originalCommitTimestamp: see APPLYING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP
- originalCommitToNowTime: see APPLYING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP minus NOW()
- startTimestamp: see APPLYING_TRANSACTION_START_APPLY_TIMESTAMP
- transaction: see APPLYING_TRANSACTION

The lastProcessed section has the following information about the last transaction processed by the worker:

- bufferTime: LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP minus LAST_PROCESSED_TRANSACTION_START_BUFFER_TIMESTAMP
- endTimestamp: see LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP
- immediateCommitTimestamp: see LAST_PROCESSED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP
- immediateCommitToEndTime: LAST_PROCESSED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP minus LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP
- originalCommitTimestamp: see LAST_PROCESSED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP
- originalCommitToEndTime: LAST_PROCESSED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP minus LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP
- startTimestamp: see LAST_PROCESSED_TRANSACTION_START_BUFFER_TIMESTAMP
- transaction: see LAST_PROCESSED_TRANSACTION

If parallel applier workers are enabled, then the number of objects in the workers array in transactions or recovery matches the number of configured workers and an additional coordinator object is included. The information shown matches the information in the replication_applier_status_by_coordinator table. The object can contain:

The currentlyProcessing section has the following information about the transaction being processed by the worker:

- immediateCommitTimestamp: see PROCESSING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP
- immediateCommitToNowTime: PROCESSING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP minus NOW()
- originalCommitTimestamp: see PROCESSING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP
- originalCommitToNowTime: PROCESSING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP minus NOW()
- startTimestamp: see PROCESSING_TRANSACTION_START_BUFFER_TIMESTAMP

- transaction: see PROCESSING_TRANSACTION

worker objects have the following information if an error was detected in the replication_applier_status_by_worker table:

- lastErrno: see LAST_ERROR_NUMBER
- lastError: see LAST_ERROR_MESSAGE
- lastErrorTimestamp: see LAST_ERROR_TIMESTAMP

connection objects have the following information if an error was detected in the replication_connection_status table:

- lastErrno: see LAST_ERROR_NUMBER
- lastError: see LAST_ERROR_MESSAGE
- lastErrorTimestamp: see LAST_ERROR_TIMESTAMP

coordinator objects have the following information if an error was detected in the replication_applier_status_by_coordinator table:

- lastErrno: see LAST_ERROR_NUMBER
- lastError: see LAST_ERROR_MESSAGE
- lastErrorTimestamp: see LAST_ERROR_TIMESTAMP

Using cluster.describe()

To get information about the structure of the InnoDB cluster itself, use the *Cluster*.describe() function:

```
mysql-js> cluster.describe();
{
    "clusterName": "testCluster",
    "defaultReplicaSet": {
        "name": "default",
        "topology": [
            {
                "address": "ic-1:3306",
                "label": "ic-1:3306",
                "role": "HA"
            },
            {
                "address": "ic-2:3306",
                "label": "ic-1:2306",
                "role": "HA"
            },
            {
                "address": "ic-3:3306",
                "label": "ic-3:3306",
                "role": "HA"
            }
        ]
    }
}
```

The output from this function shows the structure of the InnoDB cluster including all of its configuration information, and so on. The address, label and role values match those described at Checking a cluster's Status with *Cluster*.status() .

Super Read-only and Instances

Whenever Group Replication stops, the `super_read_only` variable is set to `ON` to ensure no writes are made to the instance. When you try to use such an instance with the following AdminAPI commands you are given the choice to set `super_read_only=OFF` on the instance:

- `dba.configureInstance()`
- `dba.configureLocalInstance()`
- `dba.createCluster()`
- `dba.rebootClusterFromCompleteOutage()`
- `dba.dropMetadataSchema()`

When AdminAPI encounters an instance which has `super_read_only=ON`, in interactive mode you are given the choice to set `super_read_only=OFF`. For example:

```
mysql-js> var myCluster = dba.createCluster('testCluster')
A new InnoDB cluster will be created on instance 'ic@ic-1:3306'.

The MySQL instance at 'ic@ic-1:3306' currently has the super_read_only
system variable set to protect it from inadvertent updates from applications.
You must first unset it to be able to perform any changes to this instance.
For more information see: https://dev.mysql.com/doc/refman/en/server-system-variables.html#sysvar_super_rea

Note: there are open sessions to 'ic@ic-1:3306'.
You may want to kill these sessions to prevent them from performing unexpected updates:

1 open session(s) of 'ic@ic-1:3306'.

Do you want to disable super_read_only and continue? [y|N]:
```

The number of current active sessions to the instance is shown. You must ensure that no applications might write to the instance inadvertently. By answering `y` you confirm that AdminAPI can write to the instance. If there is more than one open session to the instance listed, exercise caution before permitting AdminAPI to set `super_read_only=OFF`.

To force the function to set `super_read_only=OFF` in a script, pass the `clearReadOnly` option set to `true`. For example `dba.configureInstance(`*`instance`*`, {clearReadOnly: true}).`

Managing Sandbox Instances

Once a sandbox instance is running, it is possible to change its status at any time using the following:

- To stop a sandbox instance use `dba.stopSandboxInstance(`*`instance`*`)`. This stops the instance gracefully, unlike `dba.killSandboxInstance(`*`instance`*`)`.
- To start a sandbox instance use `dba.startSandboxInstance(`*`instance`*`)`.
- To kill a sandbox instance use `dba.killSandboxInstance(`*`instance`*`)`. This stops the instance without gracefully stopping it and is useful in simulating unexpected halts.
- To delete a sandbox instance use `dba.deleteSandboxInstance(`*`instance`*`)`. This completely removes the sandbox instance from your file system.

Removing Instances from the InnoDB Cluster

You can remove an instance from a cluster at any time should you wish to do so. This can be done with the *`Cluster`*`.removeInstance(`*`instance`*`)` method, as in the following example:

```
mysql-js> cluster.removeInstance('root@localhost:3310')

The instance will be removed from the InnoDB cluster. Depending on the instance
being the Seed or not, the Metadata session might become invalid. If so, please
start a new session to the Metadata Storage R/W instance.

Attempting to leave from the Group Replication group...

The instance 'localhost:3310' was successfully removed from the cluster.
```

You can optionally pass in the `interactive` option to control whether you are prompted to confirm the removal of the instance from the cluster. In interactive mode, you are prompted to continue with the removal of the instance (or not) in case it is not reachable. The *`cluster`*`.removeInstance()` operation ensures that the instance is removed from the metadata of all the cluster members which are `ONLINE`, and the instance itself.

When the instance being removed has transactions which still need to be applied, AdminAPI waits for up to the number of seconds configured by the MySQL Shell `dba.gtidWaitTimeout` option for transactions (GTIDs) to be applied. The MySQL Shell `dba.gtidWaitTimeout` option has a default value of 60 seconds, see Configuring MySQL Shell for information on changing the default. If the timeout value defined by `dba.gtidWaitTimeout` is reached when waiting for transactions to be applied and the `force` option is `false` (or not defined) then an error is issued and the remove operation is aborted. If the timeout value defined by `dba.gtidWaitTimeout` is reached when waiting for transactions to be applied and the `force` option is set to `true` then the operation continues without an error and removes the instance from the cluster.

Important

The `force` option should only be used with *`Cluster`*`.removeInstance(`*`instance`*`)` when you want to ignore any errors, for example unprocessed transactions or an instance being `UNREACHABLE`, and do not plan to reuse the instance with the cluster. Ignoring errors when removing an instance from the cluster could result in an instance which is not in synchrony with the cluster, preventing it from rejoining the cluster at a later time. Only use the `force` option when you plan to no longer use the instance with the cluster, in all other cases you should always try to recover the instance and only remove it when it is available and healthy, in other words with the status `ONLINE`.

Customizing InnoDB clusters

When you create a cluster and add instances to it, values such as the group name, the local address, and the seed instances are configured automatically by AdminAPI. These default values are recommended for most deployments, but advanced users can override the defaults by passing the following options to the `dba.createCluster()` and *`Cluster`*`.addInstance()`.

To customize the name of the replication group created by InnoDB cluster, pass the `groupName` option to the `dba.createCluster()` command. This sets the `group_replication_group_name` system variable. The name must be a valid UUID.

To customize the address which an instance provides for connections from other instances, pass the `localAddress` option to the `dba.createCluster()` and `cluster.addInstance()` commands. Specify the address in the format *`host:port`*. This sets the `group_replication_local_address` system variable on the instance. The address must be accessible to all instances in the cluster, and must be reserved for internal cluster communication only. In other words do not use this address for communication with the instance.

To customize the instances used as seeds when an instance joins the cluster, pass the `groupSeeds` option to the `dba.createCluster()` and `cluster.addInstance()` commands. Seed instances are contacted when a new instance joins a cluster and used to provide data to the new instance.

The addresses are specified as a comma separated list such as `host1:port1`,`host2:port2`. This configures the `group_replication_group_seeds` system variable.

For more information see the documentation of the system variables configured by these AdminAPI options.

Rejoining a Cluster

If an instance leaves the cluster, for example because it lost connection, and for some reason it could not automatically rejoin the cluster, it might be necessary to rejoin it to the cluster at a later stage. To rejoin an instance to a cluster issue *`Cluster`*`.rejoinInstance(`*`instance`*`)`.

Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See Super Read-only and Instances for more information.

In the case where an instance has not had it's configuration persisted (see Persisting Settings), upon restart the instance does not rejoin the cluster automatically. The solution is to issue `cluster.rejoinInstance()` so that the instance is added to the cluster again and ensure the changes are persisted. Once the InnoDB cluster configuration is persisted to the instance's option file it rejoins the cluster automatically.

If you are rejoining an instance which has changed in some way then you might have to modify the instance to make the rejoin process work correctly. For example, when you restore a MySQL Enterprise Backup backup, the `server_uuid` changes. Attempting to rejoin such an instance fails because InnoDB cluster instances are identified by the `server_uuid` variable. In such a situation, information about the instance's old `server_uuid` must be removed from the InnoDB cluster metadata and then a *`Cluster`*`.rescan()` must be executed to add the instance to the metadata using it's new `server_uuid`. For example:

```
cluster.removeInstance("root@instanceWithOldUUID:3306", {force: true})

cluster.rescan()
```

In this case you must pass the `force` option to the *`Cluster`*`.removeInstance()` method because the instance is unreachable from the cluster's perspective and we want to remove it from the InnoDB cluster metadata anyway.

Restoring a Cluster from Quorum Loss

If an instance (or instances) fail, then a cluster can lose its quorum, which is the ability to vote in a new primary. If you have an instance which contains the InnoDB cluster metadata, it is possible to restore the cluster. This assumes you can connect to an instance that contains the InnoDB cluster metadata, and that instance can contact the other instances you want to use to restore the cluster.

Important

This operation is potentially dangerous because it can create a split-brain scenario if incorrectly used and should be considered a last resort. Make absolutely sure that there are no partitions of this group that are still operating somewhere in the network, but not accessible from your location.

You connect to an instance which contains the cluster's metadata, then use the *`Cluster`*`.forceQuorumUsingPartitionOf(`*`instance`*`)` operation, which restores the cluster based on the metadata on *`instance`*, and then all the instances that are `ONLINE` from the point of view of the given instance definition are added to the restored cluster.

```
mysql-js> cluster.forceQuorumUsingPartitionOf("ic@ic-1:3306")

  Restoring replicaset 'default' from loss of quorum, by using the partition composed of [ic@ic-1:3306]

  Please provide the password for 'ic@ic-1:3306': ******
  Restoring the InnoDB cluster ...

  The InnoDB cluster was successfully restored using the partition from the instance 'ic@ic-1:3306'.

  WARNING: To avoid a split-brain scenario, ensure that all other members of the replicaset
  are removed or joined back to the group that was restored.
```

In the event that an instance is not automatically added to the cluster, for example if its settings were not persisted, use `Cluster.rejoinInstance()` to manually add the instance back to the cluster.

The restored cluster might not, and does not have to, consist of all of the original instances which made up the cluster. For example, if the original cluster consisted of the following five instances:

- `ic-1`
- `ic-2`
- `ic-3`
- `ic-4`
- `ic-5`

and the cluster experiences a split-brain scenario, with `ic-1`, `ic-2`, and `ic-3` forming one partition while `ic-4` and `ic-5` form another partition. If you connect to `ic-1` and issue `Cluster.forceQuorumUsingPartitionOf('ic@ic-1:3306')` to restore the cluster the reulting cluster would consist of these three instances:

- `ic-1`
- `ic-2`
- `ic-3`

because `ic-1` sees `ic-2` and `ic-3` as `ONLINE` and does not see `ic-4` and `ic-5`.

Rebooting a Cluster from a Major Outage

If your cluster suffers from a complete outage, you can ensure it is reconfigured correctly using `dba.rebootClusterFromCompleteOutage()`. In the event that a cluster has completely stopped, the instances must be started and only then can the cluster be started. For example if the machine a sandbox cluster was running on has been restarted, and the instances were at ports 3310, 3320 and 3330, issue:

```
mysql-js> dba.startSandboxInstance(3310)
mysql-js> dba.startSandboxInstance(3320)
mysql-js> dba.startSandboxInstance(3330)
```

This ensures the sandbox instances are running. In the case of a production deployment you would have to start the instances outside of MySQL Shell. Once the instances have started, connect to an instance and run MySQL Shell. Then restart the cluster by issuing:

```
mysql-js> var cluster = dba.rebootClusterFromCompleteOutage();
```

Tip

If the instance has `super_read_only=ON` then you might need to confirm that AdminAPI can set `super_read_only=OFF`. See Super Read-only and Instances for more information.

This ensures the cluster is correctly reconfigured after a complete outage. It uses the instance that MySQL Shell is connected to as the new seed instance and recovers the cluster based on the existing metadata of that instance.

If this process fails, and the cluster metadata has become badly corrupted, you might need to drop the metadata and create the cluster again from scratch. You can drop the cluster metadata using `dba.dropMetadataSchema()`.

Warning

The `dba.dropMetadataSchema()` method should only be used as a last resort, when it is not possible to restore the cluster. It cannot be undone.

Rescanning a Cluster

If you make configuration changes to a cluster outside of the AdminAPI commands, for example by changing an instance's configuration manually to resolve configuration issues or after the loss of an instance, you need to update the InnoDB cluster metadata so that it matches the current configuration of instances. In these cases, use the *`Cluster`*`.rescan()` operation, which enables you to update the InnoDB cluster metadata either manually or using an interactive wizard. The *`Cluster`*`.rescan()` operation can detect new active instances that are not registered in the metadata and add them, or obsolete instances (no longer active) still registered in the metadata, and remove them. You can automatically update the metadata depending on the instances found by the command, or you can specify a list of instance addresses to either add to the metadata or remove from the metadata. You can also update the topology mode stored in the metadata, for example after changing from single-primary mode to multi-primary mode outside of AdminAPI.

The syntax of the command is *`Cluster`*`.rescan([options])`. The `options` dictionary supports the following:

- `interactive`: boolean value used to disable or enable the wizards in the command execution. Controls whether prompts and confirmations are provided. The default value is equal to MySQL Shell wizard mode, specified by `shell.options.useWizards`.
- `addInstances`: list with the connection data of the new active instances to add to the metadata, or “auto” to automatically add missing instances to the metadata. The value “auto” is case-insensitive.
  - Instances specified in the list are added to the metadata, without prompting for confirmation
  - In interactive mode, you are prompted to confirm the addition of newly discovered instances that are not included in the `addInstances` option
  - In non-interactive mode, newly discovered instances that are not included in the `addInstances` option are reported in the output, but you are not prompted to add them
- `removeInstances`: list with the connection data of the obsolete instances to remove from the metadata, or “auto” to automatically remove obsolete instances from the metadata.
  - Instances specified in the list are removed from the metadata, without prompting for confirmation
  - In interactive mode, you are prompted to confirm the removal of obsolete instances that are not included in the `removeInstances` option
  - In non-interactive mode, obsolete instances that are not included in the `removeInstances` option are reported in the output but you are not prompted to remove them

- `updateTopologyMode`: boolean value used to indicate if the topology mode (single-primary or multi-primary) in the metadata should be updated (true) or not (false) to match the one being used by the cluster. By default, the metadata is not updated (false).
  - If the value is `true` then the InnoDB cluster metadata is compared to the current mode being used by Group Replication, and the metadata is updated if necessary. Use this option to update the metadata after making changes to the topology mode of your cluster outside of AdminAPI.
  - If the value is `false` then InnoDB cluster metadata about the cluster's topology mode is not updated even if it is different from the topology used by the cluster's Group Replication group
  - If the option is not specified and the topology mode in the metadata is different from the topology used by the cluster's Group Replication group, then:
    - In interactive mode, you are prompted to confirm the update of the topology mode in the metadata
    - In non-interactive mode, if there is a difference between the topology used by the cluster's Group Replication group and the InnoDB cluster metadata, it is reported and no changes are made to the metadata
  - When the metadata topology mode is updated to match the Group Replication mode, the auto-increment settings on all instances are updated as described at InnoDB cluster and Auto-increment.

Checking Instance State

The `cluster.checkInstanceState()` function can be used to to verify the existing data on an instance does not prevent it from joining a cluster. This process works by validating the instance's global transaction identifier (GTID) state compared to the GTIDs already processed by the cluster. For more information on GTIDs see Section 17.1.3.1, “GTID Format and Storage”. This check enables you to determine if an instance which has processed transactions can be added to the cluster.

The following demonstrates issuing this in a running MySQL Shell:

```
mysql-js> cluster.checkInstanceState('ic@ic-4:3306')
```

The output of this function can be one of the following:

- OK new: the instance has not executed any GTID transactions, therefore it cannot conflict with the GTIDs executed by the cluster
- OK recoverable: the instance has executed GTIDs which do not conflict with the executed GTIDs of the cluster seed instances
- ERROR diverged: the instance has executed GTIDs which diverge with the executed GTIDs of the cluster seed instances
- ERROR lost_transactions: the instance has more executed GTIDs than the executed GTIDs of the cluster seed instances

Instances with an OK status can be added to the cluster because any data on the instance is consistent with the cluster. In other words the instance being checked has not executed any transactions which conflict with the GTIDs executed by the cluster, and can be recovered to the same state as the rest of the cluster instances.

Dissolving an InnoDB Cluster

To dissolve an InnoDB cluster you connect to a read-write instance, for example the primary in a single-primary cluster, and use the *`Cluster`*`.dissolve()` command. This removes all metadata and

configuration associated with the cluster, and disables Group Replication on the instances. Any data that was replicated between the instances is not removed.

Important

There is no way to undo the dissolving of a cluster. To create it again use `dba.createCluster()`.

The *`Cluster`*`.dissolve()` operation can only configure instances which are `ONLINE` or reachable. If members of a cluster cannot be reached by the member where you issued the *`Cluster`*`.dissolve()` command you have to decide how the dissolve operation should proceed. If there is any chance you want to rejoin any instances that are identified as missing from the cluster, it is strongly recommended to cancel the dissolve operation and first bring the missing instances back online, before proceeding with a dissolve operation. This ensures that all instances can have their metadata updated correctly, and that there is no chance of a split-brain situation. However, if the instances from the cluster which cannot be reached have permanently left the cluster there could be no choice but to force the dissolve operation, which means that the missing instances are ignored and only online instances are affected by the operation.

Warning

Forcing the dissolve operation to ignore cluster instances can result in instances which could not be reached during the dissolve operation continuing to operate, creating the risk of a split-brain situation. Only ever force a dissolve operation to ignore missing instances if you are sure there is no chance of the instance coming online again.

In interactive mode, if members of a cluster are not reachable during a dissolve operation then an interactive prompt is displayed, for example:

```
mysql-js> Cluster.dissolve()
The cluster still has the following registered ReplicaSets:
{
    "clusterName": "testCluster",
    "defaultReplicaSet": {
        "name": "default",
        "topology": [
            {
                "address": "ic-1:3306",
                "label": "ic-1:3306",
                "role": "HA"
            },
            {
                "address": "ic-2:3306",
                "label": "ic-2:3306",
                "role": "HA"
            },
            {
                "address": "ic-3:3306",
                "label": "ic-3:3306",
                "role": "HA"
            }
        ]
    }
}
WARNING: You are about to dissolve the whole cluster and lose the high
availability features provided by it. This operation cannot be reverted. All
members will be removed from their ReplicaSet and replication will be stopped,
internal recovery user accounts and the cluster metadata will be dropped. User
data will be maintained intact in all instances.

Are you sure you want to dissolve the cluster? [y/N]: y

ERROR: The instance 'ic-2:3306' cannot be removed because it is on a '(MISSING)'
state. Please bring the instance back ONLINE and try to dissolve the cluster
again. If the instance is permanently not reachable, then you can choose to
```

```
proceed with the operation and only remove the instance from the Cluster
Metadata.

Do you want to continue anyway (only the instance metadata will be removed)?
[y/N]: y

Instance 'ic-3:3306' is attempting to leave the cluster...  Instance 'ic-1:3306'
is attempting to leave the cluster...

WARNING: The cluster was successfully dissolved, but the following instance was
skipped: 'ic-2:3306'. Please make sure this instance is permanently unavailable
or take any necessary manual action to ensure the cluster is fully dissolved.
```

In this example, the cluster consisted of three instances, one of which was offline when dissolve was issued. The error is caught, and you are given the choice how to proceed. In this case the missing `ic-2` instance is ignored and the reachable members have their metadata updated.

When MySQL Shell is running in non-interactive mode, for example when running a batch file, you can configure the behavior of the `Cluster.dissolve()` operation using the `force` option. To force the dissolve operation to ignore any instances which are unreachable, issue:

```
mysql-js> Cluster.dissolve({force: true})
```

Any instances which can be reached are removed from the cluster, and any unreachable instances are ignored. The warnings in this section about forcing the removal of missing instances from a cluster apply equally to this technique of forcing the dissolve operation.

You can also use the `interactive` option with the `Cluster.dissolve()` operation to override the mode which MySQL Shell is running in, for example to make the interactive prompt appear when running a batch script. For example:

```
mysql-js> Cluster.dissolve({interactive: true})
```

The `dba.gtidWaitTimeout` MySQL Shell option configures how long the `Cluster.dissolve()` operation waits for cluster transactions to be applied before removing a target instance from the cluster, but only if the target instance is `ONLINE`. An error is issued if the timeout is reached when waiting for cluster transactions to be applied on any of the instances being removed, except if force: true is used, which skips the error in that case.

Note

After issuing `cluster.dissolve()`, any variable assigned to the `Cluster` object is no longer valid.

Securing your Cluster

Server instances can be configured to use secure connections. For general information on using SSL with MySQL see Section 6.4, “Using Encrypted Connections”. This section explains how to configure a cluster to use SSL. An additional security possibility is to configure which servers can access the cluster, see Creating a Whitelist of Servers.

Important

Once you have configured a cluster to use SSL you must add the servers to the `ipWhitelist`.

When using `dba.createCluster()` to set up a cluster, if the server instance provides SSL encryption then it is automatically enabled on the seed instance. Pass the `memberSslMode` option to the `dba.createCluster()` method to specify a different SSL mode. The SSL mode of a cluster can only be set at the time of creation. The `memberSslMode` option is a string that configures the SSL mode to be used, it defaults to `AUTO`. The permitted values are `DISABLED`, `REQUIRED`, and `AUTO`. These modes are defined as:

- Setting `createCluster({memberSslMode:'DISABLED'})` ensures SSL encryption is disabled for the seed instance in the cluster.
- Setting `createCluster({memberSslMode:'REQUIRED'})` then SSL encryption is enabled for the seed instance in the cluster. If it cannot be enabled an error is raised.
- Setting `createCluster({memberSslMode:'AUTO'})` (the default) then SSL encryption is automatically enabled if the server instance supports it, or disabled if the server does not support it.

Note

When using the commercial version of MySQL, SSL is enabled by default and you might need to configure the whitelist for all instances. See Creating a Whitelist of Servers.

When you issue the `cluster.addInstance()` and `cluster.rejoinInstance()` commands, SSL encryption on the instance is enabled or disabled based on the setting found for the seed instance.

When using `createCluster()` with the `adoptFromGR` option to adopt an existing Group Replication group, no SSL settings are changed on the adopted cluster:

- `memberSslMode` cannot be used with `adoptFromGR`.
- If the SSL settings of the adopted cluster are different from the ones supported by the MySQL Shell, in other words SSL for Group Replication recovery and Group Communication, both settings are not modified. This means you are not be able to add new instances to the cluster, unless you change the settings manually for the adopted cluster.

MySQL Shell always enables or disables SSL for the cluster for both Group Replication recovery and Group Communication, see Section 18.5.2, “Secure Socket Layer Support (SSL)”. A verification is performed and an error issued in case those settings are different for the seed instance (for example as the result of a `dba.createCluster()` using `adoptFromGR`) when adding a new instance to the cluster. SSL encryption must be enabled or disabled for all instances in the cluster. Verifications are performed to ensure that this invariant holds when adding a new instance to the cluster.

The `deploySandboxInstance()` command attempts to deploy sandbox instances with SSL encryption support by default. If it is not possible, the server instance is deployed without SSL support. Use the `ignoreSslError` option set to false to ensure that sandbox instances are deployed with SSL support, issuing an error if SSL support cannot be provided. When `ignoreSslError` is true, which is the default, no error is issued during the operation if the SSL support cannot be provided and the server instance is deployed without SSL support.

Creating a Whitelist of Servers

When using a cluster's `createCluster()`, `addInstance()`, and `rejoinInstance()` methods you can optionally specify a list of approved servers that belong to the cluster, referred to as a whitelist. By specifying the whitelist explicitly in this way you can increase the security of your cluster because only servers in the whitelist can connect to the cluster. Using the `ipWhitelist` option configures the `group_replication_ip_whitelist` system variable on the instance. By default, if not specified explicitly, the whitelist is automatically set to the private network addresses that the server has network interfaces on. To configure the whitelist, specify the servers to add with the `ipWhitelist` option when using the method. Pass the servers as a comma separated list, surrounded by quotes. For example:

```
mysql-js> cluster.addInstance("ic@ic-3:3306", {ipWhitelist: "203.0.113.0/24, 198.51.100.110"})
```

This configures the instance to only accept connections from servers at addresses `203.0.113.0/24` and `198.51.100.110`. The whitelist can also include host names, which are resolved only when a connection request is made by another server.

Warning

Host names are inherently less secure than IP addresses in a whitelist. MySQL carries out FCrDNS verification, which provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your whitelist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers, are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

Scripting AdminAPI

You can automate cluster configuration with scripts, which can be run using MySQL Shell. For example:

```
shell> mysqlsh -f setup-innodb-cluster.js
```

Note

Any command line options specified after the script file name are passed to the script and *not* to MySQL Shell. You can access those options using the `os.argv` array in JavaScript, or the `sys.argv` array in Python. In both cases, the first option picked up in the array is the script name.

The contents of an example script file is shown here:

```
print('MySQL InnoDB cluster sandbox set up\n');
print('==================================\n');
print('Setting up a MySQL InnoDB cluster with 3 MySQL Server sandbox instances.\n');
print('The instances will be installed in ~/mysql-sandboxes.\n');
print('They will run on ports 3310, 3320 and 3330.\n\n');

var dbPass = shell.prompt('Please enter a password for the MySQL root account: ', {type:"password"});

try {
   print('\nDeploying the sandbox instances.');
   dba.deploySandboxInstance(3310, {password: dbPass});
   print('.');
   dba.deploySandboxInstance(3320, {password: dbPass});
   print('.');
   dba.deploySandboxInstance(3330, {password: dbPass});
   print('.\nSandbox instances deployed successfully.\n\n');

   print('Setting up InnoDB cluster...\n');
   shell.connect('root@localhost:3310', dbPass);

   var cluster = dba.createCluster("prodCluster");

   print('Adding instances to the cluster.');
   cluster.addInstance({user: "root", host: "localhost", port: 3320, password: dbPass});
   print('.');
   cluster.addInstance({user: "root", host: "localhost", port: 3330, password: dbPass});
   print('.\nInstances successfully added to the cluster.');

   print('\nInnoDB cluster deployed successfully.\n');
} catch(e) {
   print('\nThe InnoDB cluster could not be created.\n\nError: ' +
   + e.message + '\n');
}
```

Configuring the Election Process

You can optionally configure how a single-primary cluster elects a new primary, for example to prefer one instance as the new primary to fail over to. Use the `memberWeight` option and pass it to the

`dba.createCluster()` and `Cluster.addInstance()` methods when creating your cluster. The `memberWeight` option accepts an integer value between 0 and 100, which is a percentage weight for automatic primary election on failover. When an instance has a higher precentage number set by `memberWeight`, it is more likely to be elected as primary in a single-primary cluster. When a primary election takes place, if multiple instances have the same `memberWeight` value, the instances are then prioritized based on their server UUID in lexicographical order (the lowest) and by picking the first one.

Setting the value of `memberWeight` configures the `group_replication_member_weight` system variable on the instance. Group Replication limits the value range from 0 to 100, automatically adjusting it if a higher or lower value is provided. Group Replication uses a default value of 50 if no value is provided. See Section 18.4.1.1, “Single-Primary Mode” for more information.

For example to configure a cluster where `ic-3` is the preferred instance to fail over to in the event that `ic-1`, the current primary, leaves the cluster unexpectedly use `memberWeight` as follows:

```
dba.createCluster('cluster1', {memberWeight:35})
var mycluster = dba.getCluster()
mycluster.addInstance('ic@ic2', {memberWeight:25})
mycluster.addInstance('ic@ic3', {memberWeight:50})
```

Configuring Failover Consistency

Group Replication provides the ability to specify the failover guarantees (eventual or “read your writes”) if a primary failover happens in single-primary mode (see Section 18.4.3.2, “Configuring Transaction Consistency Guarantees”). You can configure the failover guarantees of an InnoDB cluster at creation by passing the `failoverConsistency` option to the `dba.createCluster()` operation, which configures the `group_replication_consistency` system variable on the seed instance. This option defines the behavior of a new fencing mechanism used when a new primary is elected in a single-primary group. The fencing restricts connections from writing and reading from the new primary until it has applied any pending backlog of changes that came from the old primary (sometimes referred to as “read your writes”). While the fencing mechanism is in place, applications effectively do not see time going backward for a short period of time while any backlog is applied. This ensures that applications do not read stale information from the newly elected primary.

The `failoverConsistency` option is only supported if the target MySQL server version is 8.0.14 or later, and instances added to a cluster which has been configured with the `failoverConsistency` option are automatically configured to have `group_replication_consistency` the same on all cluster members that have support for the option. The variable default value is controlled by Group Replication and is `EVENTUAL`, change the `failoverConsistency` option to `BEFORE_ON_PRIMARY_FAILOVER` to enable the fencing mechanism. Alternatively use `failoverConsistency=0` for `EVENTUAL` and `failoverConsistency=1` for `BEFORE_ON_PRIMARY_FAILOVER`.

Note

Using the `failoverConsistency` option on a multi-primary InnoDB cluster has no effect but is allowed because the cluster can later be changed into single-primary mode with the *`Cluster`*`.switchToSinglePrimaryMode()` operation.

Changing a Cluster's Topology

By default, an InnoDB cluster runs in single-primary mode, where the cluster has one primary server that accepts read and write queries (R/W), and all of the remaining instances in the cluster accept only read queries (R/O). When you configure a cluster to run in multi-primary mode, all of the instances in the cluster are primaries, which means that they accept both read and write queries (R/W). If a cluster has all of its instances running MySQL server version 8.0.15 or later, you can make changes to the topology of the cluster while the cluster is online. In previous versions it was necessary to completely dissolve and re-create the cluster to make the configuration changes. This uses the group action

coordinator exposed through the UDFs described at Section 18.4.2, “Configuring an Online Group”, and as such you should observe the rules for configuring online groups.

Note

multi-primary mode is considered an advanced mode

Usually a single-primary cluster elects a new primary when the current primary leaves the cluster unexpectedly, for example due to an unexpected halt. The election process is normally used to choose which of the current secondaries becomes the new primary. To override the election process and force a specific server to become the new primary, use the `Cluster.setPrimaryInstance(instance)` function, where `instance` specifies the connection to the instance which should become the new primary. This enables you to configure the underlying Group Replication group to choose a specific instance as the new primary, bypassing the election process.

You can change the mode (sometimes described as the topology) which a cluster is running in between single-primary and multi-primary using the following operations:

- `Cluster.switchToMultiPrimaryMode()`, which switches the cluster to multi-primary mode. All instances become primaries.
- `Cluster.switchToSinglePrimaryMode([instance])`, which switches the cluster to single-primary mode. If `instance` is specified, it becomes the primary and all the other instances become secondaries. If `instance` is not specified, the new primary is the instance with the highest member weight (and the lowest UUID in case of a tie on member weight).

Setting Options for InnoDB cluster

You can check and modify the settings in place for an InnoDB cluster while the instances are online. To check the current settings of a cluster, use the following operation:

- `Cluster.options()`, which lists the cluster configuration options for its ReplicaSets and instances. A boolean option `all` can also be specified to include information about all Group Replication system variables in the output.

You can configure the options of an InnoDB cluster at a cluster level or instance level, while instances remain online. This avoids the need to remove, reconfigure and then again add the instance to change InnoDB cluster options. Use the following operations:

- `Cluster.setOption(option, value)` to change the settings of all cluster instances globally or cluster global settings such as `clusterName`.
- `Cluster.setInstanceOption(instance, option, value)` to change the settings of individual cluster instances

The way which you use InnoDB cluster options with the operations listed depends on whether the option can be changed to be the same on all instances or not. These options are changeable at both the cluster (all instances) and per instance level:

- `exitStateAction`
- `memberWeight`

This option is changeable at the per instance level only:

- `label`

These options are changeable at the cluster level only:

- `failoverConsistency`

- `expelTimeout`
- `clusterName`

InnoDB cluster and Auto-increment

When you are using an instance as part of an InnoDB cluster, the `auto_increment_increment` and `auto_increment_offset` variables are configured to avoid the possibility of auto increment collisions for multi-primary clusters up to a size of 9 (the maximum supported size of a Group Replication group). The logic used to configure these variables can be summarized as:

- If the group is running in single-primary mode, then set `auto_increment_increment` to 1 and `auto_increment_offset` to 2.
- If the group is running in multi-primary mode, then when the cluster has 7 instances or less set `auto_increment_increment` to 7 and `auto_increment_offset` to 1 + `server_id` % 7. If a multi-primary cluster has 8 or more instances set `auto_increment_increment` to the number of instances and `auto_increment_offset` to 1 + `server_id` % the number of instances.

21.5 Known Limitations

This section describes the known limitations of InnoDB cluster. As InnoDB cluster uses Group Replication, you should also be aware of its limitations, see Section 18.9.2, “Group Replication Limitations”.

- If a session type is not specified when creating the global session, MySQL Shell provides automatic protocol detection which attempts to first create a NodeSession and if that fails it tries to create a ClassicSession. With an InnoDB cluster that consists of three server instances, where there is one read-write port and two read-only ports, this can cause MySQL Shell to only connect to one of the read-only instances. Therefore it is recommended to always specify the session type when creating the global session.
- When adding non-sandbox server instances (instances which you have configured manually rather than using `dba.deploySandboxInstance()`) to a cluster, MySQL Shell is not able to persist any configuration changes in the instance's configuration file. This leads to one or both of the following scenarios:

  1. The Group Replication configuration is not persisted in the instance's configuration file and upon restart the instance does not rejoin the cluster.
  2. The instance is not valid for cluster usage. Although the instance can be verified with `dba.checkInstanceConfiguration()`, and MySQL Shell makes the required configuration changes in order to make the instance ready for cluster usage, those changes are not persisted in the configuration file and so are lost once a restart happens.

  If only `a` happens, the instance does not rejoin the cluster after a restart.

  If `b` also happens, and you observe that the instance did not rejoin the cluster after a restart, you cannot use the recommended `dba.rebootClusterFromCompleteOutage()` in this situation to get the cluster back online. This is because the instance loses any configuration changes made by MySQL Shell, and because they were not persisted, the instance reverts to the previous state before being configured for the cluster. This causes Group Replication to stop responding, and eventually the command times out.

  To avoid this problem it is strongly recommended to use `dba.configureInstance()` before adding instances to a cluster in order to persist the configuration changes.
- The use of the `--defaults-extra-file` option to specify an option file is not supported by InnoDB cluster server instances.

Chapter 22 MySQL NDB Cluster 8.0

Table of Contents

22.1 NDB Cluster Overview 3293
22.1.1 NDB Cluster Core Concepts 3294
22.1.2 NDB Cluster Nodes, Node Groups, Replicas, and Partitions 3297
22.1.3 NDB Cluster Hardware, Software, and Networking Requirements 3299
22.1.4 What is New in NDB Cluster 3301
22.1.5 Options, Variables, and Parameters Added, Deprecated or Removed in NDB 8.0 3305
22.1.6 MySQL Server Using InnoDB Compared with NDB Cluster 3305
22.1.7 Known Limitations of NDB Cluster 3308
22.2 NDB Cluster Installation 3318
22.2.1 The NDB Cluster Auto-Installer 3320
22.2.2 Installation of NDB Cluster on Linux 3341
22.2.3 Installing NDB Cluster on Windows 3349
22.2.4 Initial Configuration of NDB Cluster 3358
22.2.5 Initial Startup of NDB Cluster 3360
22.2.6 NDB Cluster Example with Tables and Data 3361
22.2.7 Safe Shutdown and Restart of NDB Cluster 3364
22.2.8 Upgrading and Downgrading NDB Cluster 3365
22.3 Configuration of NDB Cluster 3366
22.3.1 Quick Test Setup of NDB Cluster 3366
22.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables 3368
22.3.3 NDB Cluster Configuration Files 3385
22.3.4 Using High-Speed Interconnects with NDB Cluster 3560
22.4 NDB Cluster Programs 3560
22.4.1 `ndbd` — The NDB Cluster Data Node Daemon 3561
22.4.2 `ndbinfo_select_all` — Select From ndbinfo Tables 3568
22.4.3 `ndbmtd` — The NDB Cluster Data Node Daemon (Multi-Threaded) 3570
22.4.4 `ndb_mgmd` — The NDB Cluster Management Server Daemon 3571
22.4.5 `ndb_mgm` — The NDB Cluster Management Client 3579
22.4.6 `ndb_blob_tool` — Check and Repair BLOB and TEXT columns of NDB Cluster Tables 3581
22.4.7 `ndb_config` — Extract NDB Cluster Configuration Information 3583
22.4.8 `ndb_delete_all` — Delete All Rows from an NDB Table 3592
22.4.9 `ndb_desc` — Describe NDB Tables 3593
22.4.10 `ndb_drop_index` — Drop Index from an NDB Table 3599
22.4.11 `ndb_drop_table` — Drop an NDB Table 3600
22.4.12 `ndb_error_reporter` — NDB Error-Reporting Utility 3600
22.4.13 `ndb_import` — Import CSV Data Into NDB 3602
22.4.14 `ndb_index_stat` — NDB Index Statistics Utility 3615
22.4.15 `ndb_move_data` — NDB Data Copy Utility 3620
22.4.16 `ndb_perror` — Obtain NDB Error Message Information 3623
22.4.17 `ndb_print_backup_file` — Print NDB Backup File Contents 3625
22.4.18 `ndb_print_file` — Print NDB Disk Data File Contents 3625
22.4.19 `ndb_print_frag_file` — Print NDB Fragment List File Contents 3626
22.4.20 `ndb_print_schema_file` — Print NDB Schema File Contents 3626
22.4.21 `ndb_print_sys_file` — Print NDB System File Contents 3627
22.4.22 `ndb_redo_log_reader` — Check and Print Content of Cluster Redo Log 3627
22.4.23 `ndb_restore` — Restore an NDB Cluster Backup 3630
22.4.24 `ndb_select_all` — Print Rows from an NDB Table 3650
22.4.25 `ndb_select_count` — Print Row Counts for NDB Tables 3654
22.4.26 `ndb_setup.py` — Start browser-based Auto-Installer for NDB Cluster 3654
22.4.27 `ndb_show_tables` — Display List of NDB Tables 3658
22.4.28 `ndb_size.pl` — NDBCLUSTER Size Requirement Estimator 3659

22.4.29 ndb_top — View CPU usage information for NDB threads 3662
22.4.30 ndb_waiter — Wait for NDB Cluster to Reach a Given Status 3667
22.4.31 Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs 3670
22.5 Management of NDB Cluster 3675
22.5.1 Summary of NDB Cluster Start Phases 3676
22.5.2 Commands in the NDB Cluster Management Client 3677
22.5.3 Online Backup of NDB Cluster 3682
22.5.4 MySQL Server Usage for NDB Cluster 3686
22.5.5 Performing a Rolling Restart of an NDB Cluster 3688
22.5.6 Event Reports Generated in NDB Cluster 3689
22.5.7 NDB Cluster Log Messages 3700
22.5.8 NDB Cluster Single User Mode 3715
22.5.9 Quick Reference: NDB Cluster SQL Statements 3716
22.5.10 ndbinfo: The NDB Cluster Information Database 3719
22.5.11 INFORMATION_SCHEMA Tables for NDB Cluster 3766
22.5.12 NDB Cluster Security Issues 3767
22.5.13 NDB Cluster Disk Data Tables 3773
22.5.14 Online Operations with ALTER TABLE in NDB Cluster 3781
22.5.15 Adding NDB Cluster Data Nodes Online 3784
22.5.16 Distributed MySQL Privileges for NDB Cluster 3795
22.5.17 NDB API Statistics Counters and Variables 3798
22.6 NDB Cluster Replication 3809
22.6.1 NDB Cluster Replication: Abbreviations and Symbols 3810
22.6.2 General Requirements for NDB Cluster Replication 3810
22.6.3 Known Issues in NDB Cluster Replication 3811
22.6.4 NDB Cluster Replication Schema and Tables 3818
22.6.5 Preparing the NDB Cluster for Replication 3821
22.6.6 Starting NDB Cluster Replication (Single Replication Channel) 3823
22.6.7 Using Two Replication Channels for NDB Cluster Replication 3825
22.6.8 Implementing Failover with NDB Cluster Replication 3826
22.6.9 NDB Cluster Backups With NDB Cluster Replication 3827
22.6.10 NDB Cluster Replication: Multi-Master and Circular Replication 3833
22.6.11 NDB Cluster Replication Conflict Resolution 3837
22.7 NDB Cluster Release Notes 3851

MySQL *NDB Cluster* is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. Recent NDB Cluster release series use version 8 of the NDB storage engine (also known as NDBCLUSTER) to enable running several computers with MySQL servers and other software in a cluster. NDB Cluster 8.0, now available as a Developer Milestone Release (DMR) beginning with version 8.0.13, incorporates version 8.0 of the NDB storage engine. NDB Cluster 7.6, is the current GA release, and uses version 7.6 of NDB. Previous GA releases still available for use in production, NDB Cluster 7.5 and NDB Cluster 7.4, incorporate NDB versions 7.5 and 7.4, respectively. NDB Cluster 7.2, which uses version 7.2 of the NDB storage engine, is a previous GA release that is currently still maintained; 7.2 users are encouraged to upgrade to NDB 7.5 or NDB 7.6. *NDB 7.1 and previous release series are no longer supported or maintained*.

Support for the NDB storage engine is not included in standard MySQL Server 8.0 binaries built by Oracle. Instead, users of NDB Cluster binaries from Oracle should upgrade to the most recent binary release of NDB Cluster for supported platforms—these include RPMs that should work with most Linux distributions. NDB Cluster 8.0 users who build from source should use the sources provided for MySQL 8.0 and build with the options required to provide NDB support. (Locations where the sources can be obtained are listed later in this section.)

Important

MySQL NDB Cluster does not support InnoDB cluster, which must be deployed using MySQL Server 8.0 with the InnoDB storage engine as well as additional

applications that are not included in the NDB Cluster distribution. MySQL Server 8.0 binaries cannot be used with MySQL NDB Cluster. For more information about deploying and using InnoDB cluster, see Chapter 21, *InnoDB Cluster*. Section 22.1.6, "MySQL Server Using InnoDB Compared with NDB Cluster", discusses differences between the `NDB` and `InnoDB` storage engines.

This chapter contains information about NDB Cluster 8.0 releases through 8.0.16-ndb-8.0.16, currently available as a Developer Preview. NDB Cluster 7.6 is the latest General Availability release, and is recommended for new deployments; for information about NDB Cluster 7.6, see What is New in NDB Cluster 7.6. For similar information about NDB Cluster 7.5, see What is New in NDB Cluster 7.5. NDB Cluster 7.4 and 7.3 are previous GA releases still supported in production; see MySQL NDB Cluster 7.3 and NDB Cluster 7.4. NDB Cluster 7.2 is a previous GA release series which is still maintained, although we recommend that new deployments for production use NDB Cluster 7.6. For more information about NDB Cluster 7.2, see MySQL NDB Cluster 7.2.

Supported Platforms. NDB Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to https://www.mysql.com/support/supportedplatforms/cluster.html.

Availability. NDB Cluster binary and source packages are available for supported platforms from https://dev.mysql.com/downloads/cluster/.

NDB Cluster release numbers. NDB 8.0 follows the same release pattern as the MySQL Server 8.0 series of releases, beginning with MySQL 8.0.13 and MySQL NDB Cluster 8.0.13. In this *Manual* and other MySQL documentation, we identify these and later NDB Cluster releases employing a version number that begins with "NDB". This version number is that of the `NDBCLUSTER` storage engine used in the NDB 8.0 release, and is the same as the MySQL 8.0 server version on which the NDB Cluster 8.0 release is based.

Version strings used in NDB Cluster software. The version string displayed by the `mysql` client supplied with the MySQL NDB Cluster distribution uses this format:

```
mysql-mysql_server_version-cluster
```

`mysql_server_version` represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 8.0 releases, this is `8.0.n`, where *`n`* is the release number. Building from source using `-DWITH_NDBCLUSTER` or the equivalent adds the `-cluster` suffix to the version string. (See Section 22.2.2.4, "Building NDB Cluster from Source on Linux", and Section 22.2.3.2, "Compiling and Installing NDB Cluster from Source on Windows".) You can see this format used in the `mysql` client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 8.0.16-cluster Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT VERSION()\G
*************************** 1. row ***************************
VERSION(): 8.0.16-cluster
1 row in set (0.00 sec)
```

The first release of NDB Cluster using MySQL 8.0 was NDB 8.0.13, which used MySQL 8.0.13.

The version string displayed by other NDB Cluster programs not normally included with the MySQL 8.0 distribution uses this format:

```
mysql-mysql_server_version ndb-ndb_engine_version
```

mysql_server_version represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 8.0 releases, this is `8.0.n`, where *n* is the release number. *ndb_engine_version* is the version of the `NDB` storage engine used by this release of the NDB Cluster software. For all NDB 8.0 releases, this number is the same as the MySQL Server version. You can see this format used in the output of the `SHOW` command in the `ndb_mgm` client, like this:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @10.0.10.6  (mysql-8.0.17 ndb-8.0.16-ndb-8.0.16, Nodegroup: 0, *)
id=2    @10.0.10.8  (mysql-8.0.17 ndb-8.0.16-ndb-8.0.16, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)

Compatibility with standard MySQL 8.0 releases. While many standard MySQL schemas and applications can work using NDB Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using NDB Cluster (see Section 22.1.7, “Known Limitations of NDB Cluster”). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, `MyISAM` or `InnoDB`—to use the `NDB` storage engine without allowing for the possibility of changes in schemas, queries, and applications. A `mysqld` compiled without `NDB` support (that is, built without `-DWITH_NDBCLUSTER_STORAGE_ENGINE` or its alias `-DWITH_NDBCLUSTER`) cannot function as a drop-in replacement for a `mysqld` that is built with it.

NDB Cluster development source trees. NDB Cluster development trees can also be accessed from https://github.com/mysql/mysql-server.

The NDB Cluster development sources maintained at https://github.com/mysql/mysql-server are licensed under the GPL. For information about obtaining MySQL sources using Git and building them yourself, see Section 2.9.3, “Installing MySQL Using a Development Source Tree”.

Note

As with MySQL Server 8.0, NDB Cluster 8.0 releases are built using `CMake`.

NDB Cluster 7.5 and NDB Cluster 7.6 are available as General Availability (GA) releases; NDB 7.6 is recommended for new deployments. NDB Cluster 7.4 and NDB Cluster 7.3 are previous GA releases which are still supported in production. NDB 7.2 is a previous GA release series which is still maintained; it is no longer recommended for new deployments. For an overview of major features added in NDB 7.6, see What is New in NDB Cluster 7.6. For similar information about NDB Cluster 7.5, see What is New in NDB Cluster 7.5. For information about previous NDB Cluster releases, see MySQL NDB Cluster 7.3 and NDB Cluster 7.4, and MySQL NDB Cluster 7.2.

The contents of this chapter are subject to revision as NDB Cluster continues to evolve. Additional information regarding NDB Cluster can be found on the MySQL website at http://www.mysql.com/products/cluster/.

Additional Resources. More information about NDB Cluster can be found in the following places:

- For answers to some commonly asked questions about NDB Cluster, see Section A.10, “MySQL 8.0 FAQ: NDB Cluster”.
- The NDB Cluster mailing list: http://lists.mysql.com/cluster.
- The NDB Cluster Forum: https://forums.mysql.com/list.php?25.

- Many NDB Cluster users and developers blog about their experiences with NDB Cluster, and make feeds of these available through PlanetMySQL.

22.1 NDB Cluster Overview

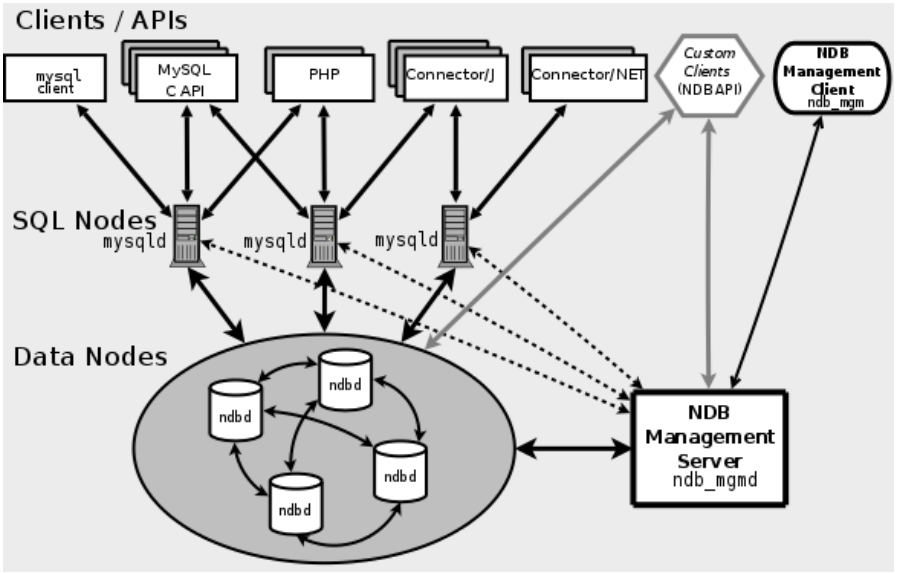
NDB Cluster is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

NDB Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

NDB Cluster integrates the standard MySQL server with an in-memory clustered storage engine called `NDB` (which stands for "*N*etwork *D*ata*B*ase"). In our documentation, the term `NDB` refers to the part of the setup that is specific to the storage engine, whereas "MySQL NDB Cluster" refers to the combination of one or more MySQL servers with the `NDB` storage engine.

An NDB Cluster consists of a set of computers, known as *hosts*, each running one or more processes. These processes, known as *nodes*, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in an NDB Cluster is shown here:

Figure 22.1 NDB Cluster Components



All these programs work together to form an NDB Cluster (see Section 22.4, "NDB Cluster Programs". When data is stored by the `NDB` storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

Although an NDB Cluster SQL node uses the `mysqld` server daemon, it differs in a number of critical respects from the `mysqld` binary supplied with the MySQL 8.0 distributions, and the two versions of `mysqld` are not interchangeable.

In addition, a MySQL server that is not connected to an NDB Cluster cannot use the `NDB` storage engine and cannot access any NDB Cluster data.

The data stored in the data nodes for NDB Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due

to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”). Rolling restarts are also used as part of the process of adding new data nodes online (see Section 22.5.15, “Adding NDB Cluster Data Nodes Online”). For more information about data nodes, how they are organized in an NDB Cluster, and how they handle and store NDB Cluster data, see Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”.

Backing up and restoring NDB Cluster databases can be done using the `NDB`-native functionality found in the NDB Cluster management client and the `ndb_restore` program included in the NDB Cluster distribution. For more information, see Section 22.5.3, “Online Backup of NDB Cluster”, and Section 22.4.23, “`ndb_restore` — Restore an NDB Cluster Backup”. You can also use the standard MySQL functionality provided for this purpose in `mysqldump` and the MySQL server. See Section 4.5.4, “`mysqldump` — A Database Backup Program”, for more information.

NDB Cluster nodes can employ different transport mechanisms for inter-node communications; TCP/IP over standard 100 Mbps or faster Ethernet hardware is used in most real-world deployments.

22.1.1 NDB Cluster Core Concepts

`NDBCLUSTER` (also known as `NDB`) is an in-memory storage engine offering high-availability and data-persistence features.

The `NDBCLUSTER` storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. NDB Cluster's `NDB` storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of NDB Cluster is configured independently of the MySQL servers. In an NDB Cluster, each part of the cluster is considered to be a *node*.

Note

In many contexts, the term “node” is used to indicate a computer, but when discussing NDB Cluster it means a *process*. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term *cluster host*.

There are three types of cluster nodes, and in a minimal NDB Cluster configuration, there will be at least three nodes, one of each of these types:

- *Management node*: The role of this type of node is to manage the other nodes within the NDB Cluster, performing such functions as providing configuration data, starting and stopping nodes, and running backups. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.

- *Data node*: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments (see Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”). For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see Section 22.4.1, “`ndbd` — The NDB Cluster Data Node Daemon”) or `ndbmtd` (see Section 22.4.3, “`ndbmtd` — The NDB Cluster Data Node Daemon (Multi-Threaded)”).

  NDB Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to NDB Cluster as an *in-memory* database). However, some NDB Cluster data can be stored on disk; see Section 22.5.13, “NDB Cluster Disk Data Tables”, for more information.

- *SQL node*: This is a node that accesses the cluster data. In the case of NDB Cluster, an SQL node is a traditional MySQL server that uses the `NDBCLUSTER` storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

  An SQL node is actually just a specialized type of *API node*, which designates any application which accesses NDB Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see Getting Started with the NDB API.

Important

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from NDB Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in NDB Cluster, see Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”.

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. NDB Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, `NDB`-specific API programs, and management clients. These are described in the next few paragraphs.

Standard MySQL clients. NDB Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as NDB Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using an NDB Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with NDB Cluster, see Using Connector/J with NDB Cluster.

NDB client programs. Client programs can be written that access NDB Cluster data directly from the `NDBCLUSTER` storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the *NDB API*, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see The NDB API.

`NDB`-specific Java applications can also be written for NDB Cluster using the *NDB Cluster Connector for Java*. This NDB Cluster Connector includes *ClusterJ*, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to `NDBCLUSTER`, and so does not require access to a MySQL Server. Support is also provided in NDB Cluster for *ClusterJPA*, an OpenJPA implementation for NDB Cluster that leverages the strengths of ClusterJ and JDBC; ID lookups and other fast operations are performed using ClusterJ (bypassing the MySQL Server), while more complex queries that can benefit from MySQL's query optimizer are sent through the MySQL Server, using JDBC. See Java and NDB Cluster, and The ClusterJ API and Data Object Model, for more information.

NDB Cluster also supports applications written in JavaScript using Node.js. The MySQL Connector for JavaScript includes adapters for direct access to the `NDB` storage engine and as well as for the MySQL Server. Applications using this Connector are typically event-driven and use a domain object model similar in many ways to that employed by ClusterJ. For more information, see MySQL NoSQL Connector for JavaScript.

The Memcache API for NDB Cluster, implemented as the loadable *ndbmemcache* storage engine for memcached version 1.6 and later, can be used to provide a persistent NDB Cluster data store, accessed using the memcache protocol.

The standard `memcached` caching engine is included in the NDB Cluster 8.0 distribution. Each `memcached` server has direct access to data stored in NDB Cluster, but is also able to cache data locally and to serve (some) requests from this local cache.

For more information, see ndbmemcache—Memcache API for NDB Cluster.

Management clients. These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the `ndb_mgm` management client supplied with NDB Cluster (see Section 22.4.5, “`ndb_mgm` — The NDB Cluster Management Client”). Such applications can be written using the *MGM API*, a C-language API that communicates directly with one or more NDB Cluster management servers. For more information, see The MGM API.

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex NDB Cluster management tasks, such restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to NDB Cluster. See MySQL™ Cluster Manager 1.4.7 User Manual, for more information.

Event logs. NDB Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in Section 22.5.6, “Event Reports Generated in NDB Cluster”. Event logs are of the two types listed here:

- *Cluster log*: Keeps a record of all desired reportable events for the cluster as a whole.
- *Node log*: A separate log which is also kept for each individual node.

Note

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

Checkpoint. Generally speaking, when data is saved to disk, it is said that a *checkpoint* has been reached. More specific to NDB Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the `NDB` storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained. These are shown in the following list:

- *Local Checkpoint (LCP)*: This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP usually occurs every few minutes; the precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

  NDB 8.0 supports partial LCPs, which can significantly improve performance under some conditions. See the descriptions of the `EnablePartialLcp` and `RecoveryWork` configuration parameters which enable partial LCPs and control the amount of storage they use.

- *Global Checkpoint (GCP)*: A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

For more information about the files and directories created by local checkpoints and global checkpoints, see NDB Cluster Data Node File System Directory Files.

22.1.2 NDB Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which NDB Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

Data node. An `ndbd` or `ndbmtd` process, which stores one or more *replicas*—that is, copies of the *partitions* (discussed later in this section) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple data node processes on a single computer, such a configuration is not usually recommended.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` or `ndbmtd` process; where mentioned, management nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

Node group. A node group consists of one or more nodes, and stores partitions, or sets of *replicas* (see next item).

The number of node groups in an NDB Cluster is not directly configurable; it is a function of the number of data nodes and of the number of replicas (`NoOfReplicas` configuration parameter), as shown here:

```
[# of node groups] = [# of data nodes] / NoOfReplicas
```

Thus, an NDB Cluster with 4 data nodes has 4 node groups if `NoOfReplicas` is set to 1 in the `config.ini` file, 2 node groups if `NoOfReplicas` is set to 2, and 1 node group if `NoOfReplicas` is set to 4. Replicas are discussed later in this section; for more information about `NoOfReplicas`, see Section 22.3.3.6, “Defining NDB Cluster Data Nodes”.

Note

All node groups in an NDB Cluster must have the same number of data nodes.

You can add new node groups (and thus new data nodes) online, to a running NDB Cluster; see Section 22.5.15, “Adding NDB Cluster Data Nodes Online”, for more information.

Partition. This is a portion of the data stored by the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

The number of partitions used by default by NDB Cluster depends on the number of data nodes and the number of LDM threads in use by the data nodes, as shown here:

```
[# of partitions] = [# of data nodes] * [# of LDM threads]
```

When using data nodes running `ndbmtd`, the number of LDM threads is controlled by the setting for `MaxNoOfExecutionThreads`. When using `ndbd` there is a single LDM thread, which means that there are as many cluster partitions as nodes participating in the cluster. This is also the case when using `ndbmtd` with `MaxNoOfExecutionThreads` set to 3 or less. (You should be aware that the number of LDM threads increases with the value of this parameter, but not in a strictly linear fashion, and that there are additional constraints on setting it; see the description of `MaxNoOfExecutionThreads` for more information.)

NDB and user-defined partitioning. NDB Cluster normally partitions `NDBCLUSTER` tables automatically. However, it is also possible to employ user-defined partitioning with `NDBCLUSTER` tables. This is subject to the following limitations:

1. Only the `KEY` and `LINEAR KEY` partitioning schemes are supported in production with `NDB` tables.

2. The maximum number of partitions that may be defined explicitly for any `NDB` table is `8 * MaxNoOfExecutionThreads * [number of node groups]`, the number of node groups in an NDB Cluster being determined as discussed previously in this section. When using `ndbd` for data node processes, setting `MaxNoOfExecutionThreads` has no effect; in such a case, it can be treated as though it were equal to 1 for purposes of performing this calculation.

   See Section 22.4.3, "`ndbmtd` — The NDB Cluster Data Node Daemon (Multi-Threaded)", for more information.

For more information relating to NDB Cluster and user-defined partitioning, see Section 22.1.7, "Known Limitations of NDB Cluster", and Section 23.6.2, "Partitioning Limitations Relating to Storage Engines".

Replica. This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a *partition replica*. The number of replicas is equal to the number of nodes per node group.

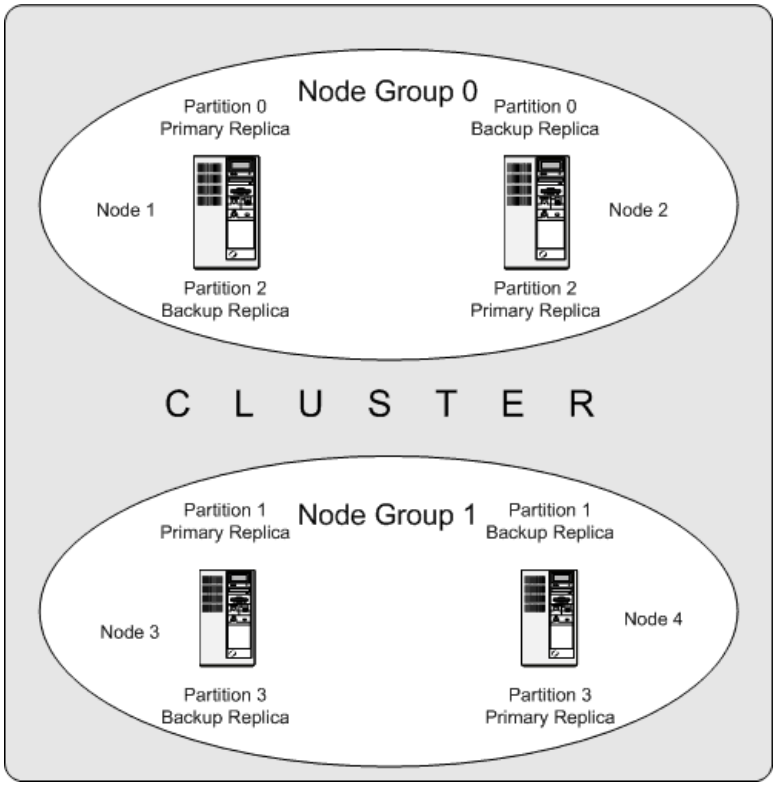
A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

The following diagram illustrates an NDB Cluster with four data nodes running `ndbd`, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1.

Note

Only data nodes are shown here; although a working NDB Cluster requires an `ndb_mgmd` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted from the figure for clarity.

Figure 22.2 NDB Cluster with Two Node Groups

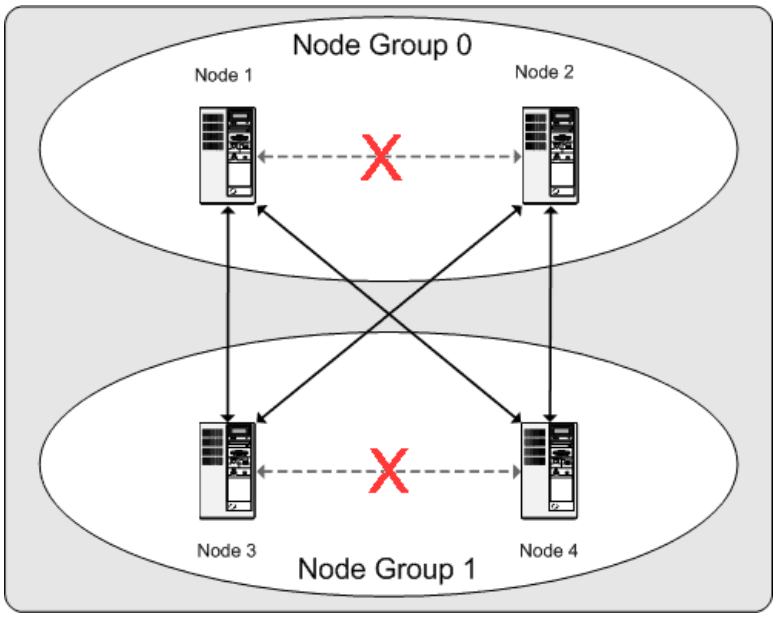


The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a *primary replica* (primary copy) is stored on node 1, and a *backup replica* (backup copy of the partition) is stored on node 2.
- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.
- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.
- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of an NDB Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

Figure 22.3 Nodes Required for a 2x2 NDB Cluster



In this example, the cluster consists of two node groups each consisting of two data nodes. Each data node is running an instance of `ndbd`. Any combination of at least one node from node group 0 and at least one node from node group 1 is sufficient to keep the cluster “alive”. However, if both nodes from a single node group fail, the combination consisting of the remaining two nodes in the other node group is not sufficient. In this situation, the cluster has lost an entire partition and so can no longer provide access to a complete set of all NDB Cluster data.

The maximum number of node groups supported for a single NDB Cluster instance is 48.

22.1.3 NDB Cluster Hardware, Software, and Networking Requirements

One of the strengths of NDB Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see Section 22.5.13, “NDB Cluster Disk Data Tables”, for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other NDB Cluster processes are relatively small.

The software requirements for NDB Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support NDB Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are

simple: all that is needed is a production release of NDB Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use NDB Cluster. We assume that you are using the binaries appropriate to your platform, available from the NDB Cluster software downloads page at https://dev.mysql.com/downloads/cluster/.

For communication between nodes, NDB Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that an NDB Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

- **Security.** Communications between NDB Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within an NDB Cluster is to run your NDB Cluster on a protected network. If you intend to use NDB Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere.

  See Section 22.5.12.1, “NDB Cluster Security and Networking Issues”, for more information.

- **Efficiency.** Setting up an NDB Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your NDB Cluster not only helps protect against unauthorized access to NDB Cluster data, it also ensures that NDB Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

Network communication and latency. NDB Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, NDB Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, an NDB Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node's data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node's slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` and `HeartbeatIntervalDbApi` for NDB Cluster, care must be taken care to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100 µs), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where NDB Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

22.1.4 What is New in NDB Cluster

The following sections describe changes in the implementation of NDB Cluster in MySQL NDB Cluster 8.0 through 8.0.16, as compared to earlier release series. NDB Cluster 8.0 is currently available in a Developer Preview release. NDB Cluster 7.6 is available as a General Availability release, as is NDB Cluster 7.5 For information about additions and other changes in NDB Cluster 7.6, see What is New in NDB Cluster 7.5; for information about new features and other changes in NDB Cluster 7.5, see What is New in NDB Cluster 7.6.

NDB Cluster 7.4 and 7.3 are recent General Availability releases, and are still supported. NDB Cluster 7.2 is a previous GA release, still supported in production for existing deployments. *NDB 7.1 and earlier releases series are no longer maintained or supported in production*. We recommend that new deployments use NDB Cluster 7.6 or NDB Cluster 7.5. For information about NDB 7.4 and NDB 7.3, see MySQL NDB Cluster 7.3 and NDB Cluster 7.4. For information about NDB 7.2 and previous NDB releases, see MySQL NDB Cluster 7.2.

What is New in NDB Cluster 8.0

Major changes and new features in NDB Cluster 8.0 which are likely to be of interest are shown in the following list:

- **INFORMATION_SCHEMA changes.** The following changes are made in the display of information about Disk Data files in the `INFORMATION_SCHEMA.FILES` table:

  - Tablespaces and log file groups are no longer represented in the `FILES` table. (These constructs are not actually files.)

  - Each data file is now represented by a single row in the `FILES` table. Each undo log file is also now represented in this table by one row only. (Previously, a row was displayed for each copy of each of these files on each data node.)

  - For rows corresponding to data files or undo log files, node ID and undo log buffer information is no longer displayed in the `EXTRA` column of the `FILES` table.

  In addition, `INFORMATION_SCHEMA` tables now are populated with tablespace statistics for MySQL Cluster tables. (Bug #27167728)

- **Error information with ndb_perror.** Removed the deprecated `--ndb` option for `perror`. Use `ndb_perror` to obtain error message information from `NDB` error codes instead. (Bug #81704, Bug #81705, Bug #23523926, Bug #23523957)

- **Development in parallel with MySQL server.** Beginning with this release, MySQL NDB Cluster is being developed in parallel with the standard MySQL 8.0 server under a new unified release model with the following features:

  - NDB 8.0 is developed in, built from, and released with the MySQL 8.0 source code tree.

  - The numbering scheme for NDB Cluster 8.0 releases follows the scheme for MySQL 8.0, starting with the current MySQL release (8.0.13).

  - Building the source with NDB support appends `-cluster` to the version string returned by `mysql -V`, as shown here:

```
shell≫ mysql -V
mysql  Ver 8.0.13-cluster for Linux on x86_64 (Source distribution)
```

NDB binaries continue to display both the MySQL Server version and the NDB engine version, like this:

```
shell> ndb_mgm -V
MySQL distrib mysql-8.0.13 ndb-8.0.13-dmr, for Linux (x86_64)
```

In MySQL Cluster NDB 8.0, these two version numbers are always the same.

To build the MySQL 8.0.13 (or later) source with NDB Cluster support, use the CMake option `-DWITH_NDBCLUSTER`.

- **Offline multithreaded index builds.** It is now possible to specify a set of cores to be used for I/O threads performing offline multithreaded builds of ordered indexes, as opposed to normal I/O duties such as file I/O , compression , or decompression. “Offline” in this context refers to building of ordered indexes performed when the parent table is not being written to; such building takes place when an `NDB` cluster performs a node or system restart, or as part of restoring a cluster from backup using `ndb_restore --rebuild-indexes`.

  In addition, the default behaviour for offline index build work is modified to use all cores available to `ndbmtd`, rather limiting itself to the core reserved for the I/O thread. Doing so can improve restart and restore times and performance, availability, and the user experience.

  This enhancement is implemented as follows:

  1. The default value for `BuildIndexThreads` is changed from 0 to 128. This means that offline ordered index builds are now multithreaded by default.

  2. The default value for `TwoPassInitialNodeRestartCopy` is changed from `false` to `true`. This means that an initial node restart first copies all data from a “live” node to one that is starting —without creating any indexes—builds ordered indexes offline, and then again synchronizes its data with the live node, that is, synchronizing twice and building indexes offline between the two synchonizations. This causes an initial node restart to behave more like the normal restart of a node, and reduces the time required for building indexes.

  3. A new thread type (`idxbld`) is defined for the `ThreadConfig` configuration parameter, to allow locking of offline index build threads to specific CPUs.

  In addition, `NDB` now distinguishes the thread types that are accessible to “ThreadConfig” by the following two criteria:

  1. Whether the thread is an execution thread. Threads of types `main`, `ldm`, `recv`, `rep`, `tc`, and `send` are execution threads; thread types `io`, `watchdog`, and `idxbld` are not.

  2. Whether the allocation of the thread to a given task is permanent or temporary. Currently all thread types except `idxbld` are permanent.

  For additonal information, see the descriptions of the parameters in the Manual. (Bug #25835748, Bug #26928111)

- **logbuffers table backup process information.** When performing an NDB backup, the `ndbinfo.logbuffers` table now displays information regarding buffer usage by the backup process on each data node. This is implemented as rows reflecting two new log types in addition to `REDO` and `DD-UNDO`. One of these rows has the log type `BACKUP-DATA`, which shows the amount of data buffer used during backup to copy fragments to backup files. The other row has the log type `BACKUP-LOG`, which displays the amount of log buffer used during the backup to record changes made after the backup has started. One each of these `log_type` rows is shown in the `logbuffers`

table for each data node in the cluster. Rows having these two log types are present in the table only while an NDB backup is currently in progress. (Bug #25822988)

- **processes table on Windows.** The process ID of the monitor process used on Windows platforms by `RESTART` to spawn and restart a `mysqld` is now shown in the `ndbinfo.processes` table as an `angel_pid`.

- **ODirectSyncFlag.** Added the `ODirectSyncFlag` configuration parameter for data nodes. When enabled, the data node treats all completed filesystem writes to the redo log as though they had been performed using `fsync`.

  Note

  This parameter has no effect if at least one of the following conditions is true:

  - `ODirect` is not enabled.
  - `InitFragmentLogFiles` is set to `SPARSE`.

  (Bug #25428560)

- **Data node log buffer size control.** Added the `--logbuffer-size` option for `ndbd` and `ndbmtd`, for use in debugging with a large number of log messages. This controls the size of the data node log buffer; the default (32K) is intended for normal operations. (Bug #89679, Bug #27550943)

- **String hashing improvements.** Prior to NDB 8.0, all string hashing was based on first transforming the string into a normalized form, then MD5-hashing the resulting binary image. This could give rise to some performance problems, for the following reasons:

  - The normalized string is always space padded to its full length. For a `VARCHAR`, this often involved adding more spaces than there were characters in the original string.
  - The string libraries were not optimized for this space padding, and added considerable overhead in some use cases.
  - The padding semantics varied between character sets, some of which were not padded to their full length.
  - The transformed string could become quite large, even without space padding; some Unicode 9.0 collations can transform a single code point into 100 bytes of character data or more.
  - Subsequent MD5 hashing consisted mainly of padding with spaces, and was not particularly efficient, possibly causing additional performance penalties by flush significant portions of the L1 cache.

  Collations provide their own hash functions, which hash the string directly without first creating a normalized string. In addition, for Unicode 9.0 collations, the hashes are computed without padding. `NDB` now takes advantage of this built-in function whenever hashing a string identified as using a Unicode 9.0 collation.

  Since, for other collations there are existing databases which are hash partitioned on the transformed string, `NDB` continues to employ the previous method for hashing strings that use these, to maintain compatibility. (Bug #89590, Bug #89604, Bug #89609, Bug #27515000, Bug #27523758, Bug #27522732)

  (See also.)

- **On-the-fly upgrades of tables using .frm files.** A table created in NDB 7.6 and earlier contains metadata in the form of a compressed `.frm` file, which is no longer supported in MySQL 8.0. To facilitate online upgrades to NDB 8.0, `NDB` performs on-the-fly translation of this metadata and

writes it into the MySQL Server's data dictionary, which enables the `mysqld` in NDB Cluster 8.0 to work with the table without preventing subsequent use of the table by a previous version of the `NDB` software.

Important

Once a table's structure has been modified in NDB 8.0, its metadata is stored using the Data Dictionary, and it can no longer be accessed by NDB 7.6 and earlier.

This enhancement also makes it possible to restore an `NDB` backup made using an earlier version to a cluster running NDB 8.0 (or later).

- **Schema synchronization of tablespace objects.** When a MySQL Server connects as an SQL node to an NDB cluster, it synchronizes its data dictionary with the information found in `NDB` dictionary.

  Previously, the only `NDB` objects synchronized on connection of a new SQL node were databases and tables; MySQL NDB Cluster 8.0.14 and later also implement schema synchronization of disk data objects including tablespaces and log file groups. Among other benefits, this eliminates the possibility of a mismatch between the MySQL data dictionary and the `NDB` dictionary following a native backup and restore, in which tablespaces and log file groups were restored to the `NDB` dictionary, but not to the MySQL Server's data dictionary.

- **Handling of NO_AUTO_CREATE_USER in mysqld options file.** An error now is written to the server log when the presence of the `NO_AUTO_CREATE_USER` value for the `sql_mode` option in the options file prevents `mysqld` from starting.

- **Handling of references to nonexistent tablespaces.** It is no longer possible to issue a `CREATE TABLE` statement that refers to a nonexistent tablespace. Such a statement now fails with an error.

- **RESET MASTER changes.** Because the MySQL Server now executes `RESET MASTER` with a global read lock, the behavior of this statement when used with NDB Cluster has changed in the following two respects:

  - It is no longer guaranteed to be synonchrous; that is, it is now possible that a read coming immediately before `RESET MASTER` is issued may not be logged until after the binary log has been rotated.

  - It now behaves identically, regardless of whether the statement is issued on the same SQL node that is writing the binary log, or on a different SQL node in the same cluster.

  Note

  `SHOW BINLOG EVENTS`, `FLUSH LOGS`, and most data definition statements continue, as they did in previous `NDB` versions, to operate in a synchronous fashion.

- **NDB table extra metadata changes.** In NDB 8.0.14 and later, the extra metadata property of an `NDB` table is used for storing serialized metadata from the MySQL data dictionary rather than storing the binary representation of the table as in previous versions. (This was a `.frm` file, no longer used by the MySQL Server—see Chapter 14, *MySQL Data Dictionary*.) As part of the work to support this change, the available size of the table's extra metadata has been increased. This means that `NDB` tables created in NDB Cluster 8.0.14 and later are not compatible with previous NDB Cluster releases. Tables created in previous releases can be used with NDB 8.0.14 and later, but cannot be opened afterwards by an earlier version.

  For more information, see Section 22.2.8, “Upgrading and Downgrading NDB Cluster”.

- **Disk data file distribution.** Beginning with NDB Cluster 8.0.14, `NDB` uses the MySQL data dictionary to make sure that disk data files and related constructs such as tablespaces and log file groups are correctly distributed between all connected SQL nodes.
- **ndb_restore options.** Beginning with NDB 8.0.16, the `--nodeid` and `--backupid` options are both required when invoking `ndb_restore`.
- **ndb_log_bin system variable.** Beginning with NDB 8.0.16, the default value of the `ndb_log_bin` system variable has changed from `TRUE` to `FALSE`.

22.1.5 Options, Variables, and Parameters Added, Deprecated or Removed in NDB 8.0

- Node Configuration Parameters Introduced in NDB 8.0
- Node Configuration Parameters Deprecated in NDB 8.0
- Node Configuration Parameters Removed in NDB 8.0
- MySQL Server Options and Variables Introduced in NDB 8.0
- MySQL Server Options and Variables Deprecated in NDB 8.0
- MySQL Server Options and Variables Removed in NDB 8.0

The next few sections contain information about `NDB` configuration parameters and NDB-specific `mysqld` options and variables that have been added to, deprecated in, or removed from NDB 8.0.

Node Configuration Parameters Introduced in NDB 8.0

No node configuration parameters have been added to NDB 8.0.

Node Configuration Parameters Deprecated in NDB 8.0

No node configuration parameters have been deprecated in NDB 8.0.

Node Configuration Parameters Removed in NDB 8.0

No node configuration parameters have been removed from NDB 8.0.

MySQL Server Options and Variables Introduced in NDB 8.0

No new system variables, status variables, or options have been added to NDB 8.0.

MySQL Server Options and Variables Deprecated in NDB 8.0

No system variables, status variables, or options have been deprecated in NDB 8.0.

MySQL Server Options and Variables Removed in NDB 8.0

No system variables, status variables, or options have been removed from NDB 8.0.

22.1.6 MySQL Server Using InnoDB Compared with NDB Cluster

MySQL Server offers a number of choices in storage engines. Since both `NDB` and `InnoDB` can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in NDB Cluster. They see `NDB` as a possible alternative or upgrade to the default `InnoDB` storage engine in MySQL 8.0. While `NDB` and `InnoDB` share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for NDB Cluster, but not all of them.

In this section, we discuss and compare some characteristics of the NDB storage engine used by NDB 8.0 with InnoDB used in MySQL 8.0. The next few sections provide a technical comparison. In many instances, decisions about when and where to use NDB Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for NDB as opposed to InnoDB back ends.

NDB Cluster 8.0 uses a mysqld based on MySQL 8.0, including support for InnoDB 1.1. While it is possible to use InnoDB tables with NDB Cluster, such tables are not clustered. It is also not possible to use programs or libraries from an NDB Cluster 8.0 distribution with MySQL Server 8.0, or the reverse.

While it is also true that some types of common business applications can be run either on NDB Cluster or on MySQL Server (most likely using the InnoDB storage engine), there are some important architectural and implementation differences. Section 22.1.6.1, “Differences Between the NDB and InnoDB Storage Engines”, provides a summary of the these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see Section 22.1.6.2, “NDB and InnoDB Workloads”. This in turn has an impact on the types of applications that better suited for use with NDB or InnoDB. See Section 22.1.6.3, “NDB and InnoDB Feature Usage Summary”, for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the NDB and MEMORY storage engines, see When to Use MEMORY or NDB Cluster.

See Chapter 16, *Alternative Storage Engines*, for additional information about MySQL storage engines.

22.1.6.1 Differences Between the NDB and InnoDB Storage Engines

The NDB storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from InnoDB in a number of ways. For those unaccustomed to working with NDB, unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, table limits, and other characteristics. These are shown in the following table:

Table 22.1 Differences between InnoDB and NDB storage engines

Feature	InnoDB (MySQL 8.0)	NDB 8.0
MySQL Server Version	8.0	8.0
InnoDB Version	InnoDB 8.0.17	InnoDB 8.0.17
NDB Cluster Version	N/A	NDB 8.0.16/8.0.16
Storage Limits	64TB	128TB
Foreign Keys	Yes	Yes
Transactions	All standard types	READ COMMITTED
MVCC	Yes	No
Data Compression	Yes	No (NDB checkpoint and backup files can be compressed)
Large Row Support (> 14K)	Supported for VARBINARY, VARCHAR, BLOB, and TEXT columns	Supported for BLOB and TEXT columns only (Using these types to store very large amounts of data can lower NDB performance)
Replication Support	Asynchronous and semisynchronous replication using MySQL Replication; MySQL Group Replication	Automatic synchronous replication within an NDB Cluster; asynchronous replication between NDB Clusters, using MySQL

Feature	InnoDB (MySQL 8.0)	NDB 8.0
		Replication (Semisynchronous replication is not supported)
Scaleout for Read Operations	Yes (MySQL Replication)	Yes (Automatic partitioning in NDB Cluster; NDB Cluster Replication)
Scaleout for Write Operations	Requires application-level partitioning (sharding)	Yes (Automatic partitioning in NDB Cluster is transparent to applications)
High Availability (HA)	Built-in, from InnoDB cluster	Yes (Designed for 99.999% uptime)
Node Failure Recovery and Failover	From MySQL Group Replication	Automatic (Key element in NDB architecture)
Time for Node Failure Recovery	30 seconds or longer	Typically < 1 second
Real-Time Performance	No	Yes
In-Memory Tables	No	Yes (Some data can optionally be stored on disk; both in-memory and disk data storage are durable)
NoSQL Access to Storage Engine	Yes	Yes (Multiple APIs, including Memcached, Node.js/JavaScript, Java, JPA, C++, and HTTP/REST)
Concurrent and Parallel Writes	Yes	Up to 48 writers, optimized for concurrent writes
Conflict Detection and Resolution (Multiple Replication Masters)	Yes (MySQL Group Replication)	Yes
Hash Indexes	No	Yes
Online Addition of Nodes	Read/write replicas using MySQL Group Replication	Yes (all node types)
Online Upgrades	Yes (using replication)	Yes
Online Schema Modifications	Yes, as part of MySQL 8.0	Yes

22.1.6.2 NDB and InnoDB Workloads

NDB Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, NDB Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the NDB and InnoDB storage engines with regard to some common types of database-driven application workloads are shown in the following table::

Table 22.2 Differences between InnoDB and NDB storage engines, common types of data-driven application workloads.

Workload	InnoDB	NDB Cluster (NDB)
High-Volume OLTP Applications	Yes	Yes
DSS Applications (data marts, analytics)	Yes	Limited (Join operations across OLTP datasets not exceeding 3TB in size)
Custom Applications	Yes	Yes

Workload	InnoDB	NDB Cluster (NDB)
Packaged Applications	Yes	Limited (should be mostly primary key access); NDB Cluster 8.0 supports foreign keys
In-Network Telecoms Applications (HLR, HSS, SDP)	No	Yes
Session Management and Caching	Yes	Yes
E-Commerce Applications	Yes	Yes
User Profile Management, AAA Protocol	Yes	Yes

22.1.6.3 NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of InnoDB with NDB, some are clearly more compatible with one storage engine than the other.

The following table lists supported application features according to the storage engine to which each feature is typically better suited.

Table 22.3 Supported application features according to the storage engine to which each feature is typically better suited

Preferred application requirements for InnoDB	Preferred application requirements for NDB
• Foreign keys **Note** NDB Cluster 8.0 supports foreign keys • Full table scans • Very large databases, rows, or transactions • Transactions other than READ COMMITTED	• Write scaling • 99.999% uptime • Online addition of nodes and online schema operations • Multiple SQL and NoSQL APIs (see NDB Cluster APIs: Overview and Concepts) • Real-time performance • Limited use of BLOB columns • Foreign keys are supported, although their use may have an impact on performance at high throughput

22.1.7 Known Limitations of NDB Cluster

In the sections that follow, we discuss known limitations in current releases of NDB Cluster as compared with the features available when using the MyISAM and InnoDB storage engines. If you check the “Cluster” category in the MySQL bugs database at http://bugs.mysql.com, you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at http://bugs.mysql.com, which we intend to correct in upcoming releases of NDB Cluster:

- NDB Cluster
- Cluster Direct API (NDBAPI)
- Cluster Disk Data
- Cluster Replication
- ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”. If we do not plan to fix the problem in NDB Cluster 8.0, we will add it to the list.

See Previous NDB Cluster Issues Resolved in NDB Cluster 7.3 for a list of issues in earlier releases that have been resolved in NDB Cluster 8.0.

Note

Limitations and other issues specific to NDB Cluster Replication are described in Section 22.6.3, “Known Issues in NDB Cluster Replication”.

22.1.7.1 Noncompliance with SQL Syntax in NDB Cluster

Some SQL statements relating to certain MySQL features produce errors when used with `NDB` tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the `NDB` storage engine or to alter an existing temporary table to use `NDB` fails with the error `Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'`.
- **Indexes and keys in NDB tables.** Keys and indexes on NDB Cluster tables are subject to the following limitations:
  - **Column width.** Attempting to create an index on an `NDB` table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning `Specified key was too long; max key length is 3072 bytes` is issued, and a `SHOW CREATE TABLE` statement shows the length of the index as 3072.
  - **TEXT and BLOB columns.** You cannot create indexes on `NDB` table columns that use any of the `TEXT` or `BLOB` data types.
  - **FULLTEXT indexes.** The `NDB` storage engine does not support `FULLTEXT` indexes, which are possible for `MyISAM` and `InnoDB` tables only.

    However, you can create indexes on `VARCHAR` columns of `NDB` tables.
  - **USING HASH keys and NULL.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column `NOT NULL`, or re-create the index without the `USING HASH` option.
  - **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an `NDB` column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see Section 22.1.7.6, “Unsupported or Missing Features in NDB Cluster”, for additional information.)
  - **BIT columns.** A `BIT` column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.
  - **AUTO_INCREMENT columns.** Like other MySQL storage engines, the `NDB` storage engine can handle a maximum of one `AUTO_INCREMENT` column per table. However, in the case of an NDB table with no explicit primary key, an `AUTO_INCREMENT` column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit `AUTO_INCREMENT` column unless that column is also declared using the `PRIMARY KEY` option. Attempting to create a table with an `AUTO_INCREMENT` column that is not the table's primary key, and using the `NDB` storage engine, fails with an error.
- **Restrictions on foreign keys.** Support for foreign key constraints in NDB 8.0 is comparable to that provided by `InnoDB`, subject to the following restrictions:

- Every column referenced as a foreign key requires an explicit unique key, if it is not the table's primary key.
- `ON UPDATE CASCADE` is not supported when the reference is to the parent table's primary key.

  This is because an update of a primary key is implemented as a delete of the old row (containing the old primary key) plus an insert of the new row (with a new primary key). This is not visible to the `NDB` kernel, which views these two rows as being the same, and thus has no way of knowing that this update should be cascaded.
- `SET DEFAULT` is not supported. (Also not supported by `InnoDB`.)
- The `NO ACTION` keywords are accepted but treated as `RESTRICT`. (Also the same as with `InnoDB`.)
- In earlier versions of NDB Cluster, when creating a table with foreign key referencing an index in another table, it sometimes appeared possible to create the foreign key even if the order of the columns in the indexes did not match, due to the fact that an appropriate error was not always returned internally. A partial fix for this issue improved the error used internally to work in most cases; however, it remains possible for this situation to occur in the event that the parent index is a unique index. (Bug #18094360)

For more information, see Section 13.1.20.6, “Using FOREIGN KEY Constraints”, and Section 1.8.3.2, “FOREIGN KEY Constraints”.

- **NDB Cluster and geometry data types.** Geometry data types (`WKT` and `WKB`) are supported for `NDB` tables. However, spatial indexes are not supported.
- **Character sets and binary log files.** Currently, the `ndb_apply_status` and `ndb_binlog_index` tables are created using the `latin1` (ASCII) character set. Because names of binary logs are recorded in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

  To work around this problem, use only Latin-1 characters when naming binary log files or setting any the `--basedir`, `--log-bin`, or `--log-bin-index` options.
- **Creating NDB tables with user-defined partitioning.** Support for user-defined partitioning in NDB Cluster is restricted to [`LINEAR`] `KEY` partitioning. Using any other partitioning type with `ENGINE=NDB` or `ENGINE=NDBCLUSTER` in a `CREATE TABLE` statement results in an error.

  It is possible to override this restriction, but doing so is not supported for use in production settings. For details, see User-defined partitioning and the NDB storage engine (NDB Cluster).

  Default partitioning scheme. All NDB Cluster tables are by default partitioned by `KEY` using the table's primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the `NDB` storage engine is used instead. For additional discussion of these and related issues, see Section 23.2.5, “KEY Partitioning”.

  `CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned `NDBCLUSTER` table not to meet either or both of the following two requirements are not permitted, and fail with an error:

  1. The table must have an explicit primary key.
  2. All columns listed in the table's partitioning expression must be part of the primary key.

  Exception. If a user-partitioned `NDBCLUSTER` table is created using an empty column-list (that is, using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

Maximum number of partitions for NDBCLUSTER tables. The maximum number of partitions that can defined for a `NDBCLUSTER` table when employing user-defined partitioning is 8 per node group. (See Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”, for more information about NDB Cluster node groups.

DROP PARTITION not supported. It is not possible to drop partitions from `NDB` tables using `ALTER TABLE ... DROP PARTITION`. The other partitioning extensions to `ALTER TABLE`—`ADD PARTITION`, `REORGANIZE PARTITION`, and `COALESCE PARTITION`—are supported for NDB tables, but use copying and so are not optimized. See Section 23.3.1, “Management of RANGE and LIST Partitions” and Section 13.1.9, “ALTER TABLE Syntax”.

- **Row-based replication.**
  When using row-based replication with NDB Cluster, binary logging cannot be disabled. That is, the `NDB` storage engine ignores the value of `sql_log_bin`.

- **JSON data type.** The MySQL `JSON` data type is supported for `NDB` tables in the `mysqld` supplied with NDB 8.0.

  An `NDB` table can have a maximum of 3 `JSON` columns.

  The NDB API has no special provision for working with `JSON` data, which it views simply as `BLOB` data. Handling data as `JSON` must be performed by the application.

22.1.7.2 Limits and Differences of NDB Cluster from Standard MySQL Limits

In this section, we list limits found in NDB Cluster that either differ from limits found in, or that are not found in, standard MySQL.

Memory usage and recovery. Memory consumed when data is inserted into an `NDB` table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A `DELETE` statement on an `NDB` table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing `OPTIMIZE TABLE`.

  A rolling restart of the cluster also frees any memory used by deleted rows. See Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”.

- A `DROP TABLE` or `TRUNCATE TABLE` operation on an `NDB` table frees the memory that was used by this table for re-use by any `NDB` table, either by the same table or by another `NDB` table.

  Note

  Recall that `TRUNCATE TABLE` drops and re-creates the table. See Section 13.1.37, “TRUNCATE TABLE Syntax”.

- **Limits imposed by the cluster's configuration.**
  A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in Section 22.3.3, “NDB Cluster Configuration Files”. Most configuration parameters can be upgraded online. These hard limits include:

  - Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).

    `DataMemory` is allocated as 32KB pages. As each `DataMemory` page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

    See Section 22.3.3.6, “Defining NDB Cluster Data Nodes”, for more information.

- The maximum number of operations that can be performed per transaction is set using the configuration parameters `MaxNoOfConcurrentOperations` and `MaxNoOfLocalOperations`.

  Note

  Bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.

- Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by `MaxNoOfOrderedIndexes`, and the maximum number of ordered indexes per table is 16.

- **Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:

  - The maximum number of data nodes is 48.

    A data node must have a node ID in the range of 1 to 48, inclusive. (Management and API nodes may use node IDs in the range 1 to 255, inclusive.)

  - The total maximum number of nodes in an NDB Cluster is 255. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

  - The maximum number of metadata objects in current versions of NDB Cluster is 20320. This limit is hard-coded.

  See Previous NDB Cluster Issues Resolved in NDB Cluster 7.3, for more information.

22.1.7.3 Limits Relating to Transaction Handling in NDB Cluster

A number of limitations exist in NDB Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The `NDBCLUSTER` storage engine supports only the `READ COMMITTED` transaction isolation level. (`InnoDB`, for example, supports `READ COMMITTED`, `READ UNCOMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.) You should keep in mind that `NDB` implements `READ COMMITTED` on a per-row basis; when a read request arrives at the data node storing the row, what is returned is the last committed version of the row at that time.

  Uncommitted data is never returned, but when a transaction modifying a number of rows commits concurrently with a transaction reading the same rows, the transaction performing the read can observe “before” values, “after” values, or both, for different rows among these, due to the fact that a given row read request can be processed either before or after the commit of the other transaction.

  To ensure that a given transaction reads only before or after values, you can impose row locks using `SELECT ... LOCK IN SHARE MODE`. In such cases, the lock is held until the owning transaction is committed. Using row locks can also cause the following issues:

  - Increased frequency of lock wait timeout errors, and reduced concurrency

  - Increased transaction processing overhead due to reads requiring a commit phase

  - Possibility of exhausting the available number of concurrent locks, which is limited by `MaxNoOfConcurrentOperations`

  `NDB` uses `READ COMMITTED` for all reads unless a modifier such as `LOCK IN SHARE MODE` or `FOR UPDATE` is used. `LOCK IN SHARE MODE` causes shared row locks to be used; `FOR UPDATE` causes

exclusive row locks to be used. Unique key reads have their locks upgraded automatically by NDB to ensure a self-consistent read; BLOB reads also employ extra locking for consistency.

See Section 22.5.3.4, “NDB Cluster Backup Troubleshooting”, for information on how NDB Cluster's implementation of transaction isolation level can affect backup and restoration of NDB databases.

- **Transactions and BLOB or TEXT columns.** NDBCLUSTER stores only part of a column value that uses any of MySQL's BLOB or TEXT data types in the table visible to MySQL; the remainder of the BLOB or TEXT is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing SELECT statements on tables that contain columns of these types:

  1. For any SELECT from an NDB Cluster table: If the SELECT includes a BLOB or TEXT column, the READ COMMITTED transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.

  2. For any SELECT which uses a unique key lookup to retrieve any columns that use any of the BLOB or TEXT data types and that is executed within a transaction, a shared read lock is held on the table for the duration of the transaction—that is, until the transaction is either committed or aborted.

     This issue does not occur for queries that use index or table scans, even against NDB tables having BLOB or TEXT columns.

     For example, consider the table t defined by the following CREATE TABLE statement:

     ```
     CREATE TABLE t (
         a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
         b INT NOT NULL,
         c INT NOT NULL,
         d TEXT,
         INDEX i(b),
         UNIQUE KEY u(c)
     ) ENGINE = NDB,
     ```

     Either of the following queries on t causes a shared read lock, because the first query uses a primary key lookup and the second uses a unique key lookup:

     ```
     SELECT * FROM t WHERE a = 1;

     SELECT * FROM t WHERE c = 1;
     ```

     However, none of the four queries shown here causes a shared read lock:

     ```
     SELECT * FROM t WHERE b = 1;

     SELECT * FROM t WHERE d = '1';

     SELECT * FROM t;

     SELECT b,c WHERE a = 1;
     ```

     This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any BLOB or TEXT columns.

     You can help minimize issues with shared read locks by avoiding queries that use unique key lookups that retrieve BLOB or TEXT columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

This behavior differs from that of other transactional storage engines such as `InnoDB` that may roll back individual statements.

- **Transactions and memory usage.**
  As noted elsewhere in this chapter, NDB Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is affected as described in the following list:

  - `TRUNCATE TABLE` is not transactional when used on `NDB` tables. If a `TRUNCATE TABLE` fails to empty the table, then it must be re-run until it is successful.

  - `DELETE FROM` (even with no `WHERE` clause) *is* transactional. For tables containing a great many rows, you may find that performance is improved by using several `DELETE FROM ... LIMIT ...` statements to "chunk" the delete operation. If your objective is to empty the table, then you may wish to use `TRUNCATE TABLE` instead.

  - **LOAD DATA statements.** `LOAD DATA` is not transactional when used on `NDB` tables.

    Important

    When executing a `LOAD DATA` statement, the `NDB` engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

  - **ALTER TABLE and transactions.** When copying an `NDB` table as part of an `ALTER TABLE`, the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)

- **Transactions and the COUNT() function.** When using NDB Cluster Replication, it is not possible to guarantee the transactional consistency of the `COUNT()` function on the slave. In other words, when performing on the master a series of statements (`INSERT`, `DELETE`, or both) that changes the number of rows in a table within a single transaction, executing `SELECT COUNT(*) FROM table` queries on the slave may yield intermediate results. This is due to the fact that `SELECT COUNT(...)` may perform dirty reads, and is not a bug in the `NDB` storage engine. (See Bug #31321 for more information.)

22.1.7.4 NDB Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 `Temporary failure, distribution changed` and similar temporary errors.

- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also Section 22.1.7.2, "Limits and Differences of NDB Cluster from Standard MySQL Limits".

22.1.7.5 Limits Associated with Database Objects in NDB Cluster

Some database objects such as tables and indexes have different limitations when using the `NDBCLUSTER` storage engine:

- **Database and table names.** When using the NDB storage engine, the maximum allowed length both for database names and for table names is 63 characters. A statement using a database name or table name longer than this limit fails with an appropriate error.
- **Number of database objects.** The maximum number of *all* NDB database objects in a single NDB Cluster—including databases, tables, and indexes—is limited to 20320.
- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) that can belong to a given table is 512.
- **Attributes per key.** The maximum number of attributes per key is 32.
- **Row size.** The maximum permitted size of any one row is 14000 bytes. Each BLOB or TEXT column contributes 256 + 8 = 264 bytes to this total.
- **BIT column storage per table.** The maximum combined width for all BIT columns used in a given NDB table is 4096.
- **FIXED column storage.** NDB Cluster 8.0 supports a maximum of 128 TB per fragment of data in FIXED columns.

22.1.7.6 Unsupported or Missing Features in NDB Cluster

A number of features supported by other storage engines are not supported for NDB tables. Trying to use any of these features in NDB Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced. Statements referencing such features, even if effectively ignored by NDB, must be syntactically and otherwise valid.

- **Index prefixes.** Prefixes on indexes are not supported for NDB tables. If a prefix is used as part of an index specification in a statement such as CREATE TABLE, ALTER TABLE, or CREATE INDEX, the prefix is not created by NDB.

  A statement containing an index prefix, and creating or modifying an NDB table, must still be syntactically valid. For example, the following statement always fails with Error 1089 Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys, regardless of storage engine:

  ```
  CREATE TABLE t1 (
      c1 INT NOT NULL,
      c2 VARCHAR(100),
      INDEX i1 (c2(500))
  );
  ```

  This happens on account of the SQL syntax rule that no index may have a prefix larger than itself.
- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in MyISAM.
- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- **Replication.** Statement-based replication is not supported. Use --binlog-format=ROW (or --binlog-format=MIXED) when setting up cluster replication. See Section 22.6, “NDB Cluster Replication”, for more information.

  Replication using global transaction identifiers (GTIDs) is not compatible with NDB Cluster, and is not supported in NDB Cluster 8.0. Do not enable GTIDs when using the NDB storage engine, as this is very likely to cause problems up to and including failure of NDB Cluster Replication.

  Semisynchronous replication is not supported in NDB Cluster.
- **Generated columns.** The NDB storage engine does not support indexes on virtual generated columns.

As with other storage engines, you can create an index on a stored generated column, but you should bear in mind that `NDB` uses `DataMemory` for storage of the generated column as well as `IndexMemory` for the index. See JSON columns and indirect indexing in NDB Cluster, for an example.

NDB Cluster writes changes in stored generated columns to the binary log, but does log not those made to virtual columns. This should not effect NDB Cluster Replication or replication between `NDB` and other MySQL storage engines.

Note

See Section 22.1.7.3, “Limits Relating to Transaction Handling in NDB Cluster”, for more information relating to limitations on transaction handling in `NDB`.

22.1.7.7 Limitations Relating to Performance in NDB Cluster

The following performance issues are specific to or especially pronounced in NDB Cluster:

- **Range scans.** There are query performance issues due to sequential access to the `NDB` storage engine; it is also relatively more expensive to do many range scans than it is with either `MyISAM` or `InnoDB`.
- **Reliability of Records in range.** The `Records in range` statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ `USE INDEX` or `FORCE INDEX` to alter the execution plan. See Section 8.9.4, “Index Hints”, for more information on how to do this.
- **Unique hash indexes.** Unique hash indexes created with `USING HASH` cannot be used for accessing a table if `NULL` is given as part of the key.

22.1.7.8 Issues Exclusive to NDB Cluster

The following are limitations specific to the `NDB` storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running `mysql` or other clients that may be accessing the cluster's SQL nodes.
- **Binary logging.**
  NDB Cluster has the following limitations or restrictions with regard to binary logging:
  - `sql_log_bin` has no effect on data operations; however, it is supported for schema operations.
  - NDB Cluster cannot produce a binary log for tables having `BLOB` columns but no primary key.
  - Only the following schema operations are logged in a cluster binary log which is *not* on the `mysqld` executing the statement:
    - `CREATE TABLE`
    - `ALTER TABLE`
    - `DROP TABLE`
    - `CREATE DATABASE` / `CREATE SCHEMA`
    - `DROP DATABASE` / `DROP SCHEMA`
    - `CREATE TABLESPACE`

- `ALTER TABLESPACE`
- `DROP TABLESPACE`
- `CREATE LOGFILE GROUP`
- `ALTER LOGFILE GROUP`
- `DROP LOGFILE GROUP`

- Schema operations (DDL statements) are rejected while any data node restarts.
- **Number of replicas.** The number of replicas, as determined by the `NoOfReplicas` data node configuration parameter, is the number of copies of all data stored by NDB Cluster. Setting this parameter to 1 means there is only a single copy; in this case, no redundancy is provided, and the loss of a data node entails loss of data. To guarantee redundancy, and thus preservation of data even if a data node fails, set this parameter to 2, which is the default and recommended value in production.

  Setting `NoOfReplicas` to a value greater than 2 is possible (to a maximum of 4) but unnecessary to guard against loss of data. In addition, *values greater than 2 for this parameter are not supported in production*.

See also Section 22.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

22.1.7.9 Limitations Relating to NDB Cluster Disk Data Storage

Disk Data object maximums and minimums. Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces: 2^{32} (4294967296)
- Maximum number of data files per tablespace: 2^{16} (65536)
- The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See Section 13.1.21, “CREATE TABLESPACE Syntax”, for more information.

In addition, when working with NDB Disk Data tables, you should be aware of the following issues regarding data files and extents:

- Data files use `DataMemory`. Usage is the same as for in-memory data.
- Data files use file descriptors. It is important to keep in mind that data files are always open, which means the file descriptors are always in use and cannot be re-used for other system tasks.
- Extents require sufficient `DiskPageBufferMemory`; you must reserve enough for this parameter to account for all memory used by all extents (number of extents times size of extents).

Disk Data tables and diskless mode. Use of Disk Data tables is not supported when running the cluster in diskless mode.

22.1.7.10 Limitations Relating to Multiple NDB Cluster Nodes

Multiple SQL nodes.
The following are issues relating to the use of multiple MySQL servers as NDB Cluster SQL nodes, and are specific to the `NDBCLUSTER` storage engine:

- **No distributed table locks.** A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)

- **ALTER TABLE operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, NDB Cluster does not support distributed table locks.)

Multiple management nodes.
When using multiple management servers:

- If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.
- When a management server starts, it first checks for any other management server in the same NDB Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server `--reload` and `--initial` startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of an NDB Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this NDB Cluster. See Section 22.5.5, "Performing a Rolling Restart of an NDB Cluster", for more information.

Multiple network addresses. Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

Note

It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one `[tcp]` section per connection in the `config.ini` file. See Section 22.3.3.10, "NDB Cluster TCP/IP Connections", for more information.

22.2 NDB Cluster Installation

This section describes the basics for planning, installing, configuring, and running an NDB Cluster. Whereas the examples in Section 22.3, "Configuration of NDB Cluster" provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable NDB Cluster which meets the *minimum* requirements for availability and safeguarding of data.

This section covers hardware and software requirements; networking issues; installation of NDB Cluster; basic configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

NDB Cluster also provides the NDB Cluster Auto-Installer, a web-based graphical installer, as part of the NDB Cluster distribution. The Auto-Installer can be used to perform basic installation and setup of an NDB Cluster on one (for testing) or more host computers. See Section 22.2.1, "The NDB Cluster Auto-Installer", for more information.

Assumptions. The following sections make a number of assumptions regarding the cluster's physical and network configuration. These assumptions are discussed in the next few paragraphs.

Cluster nodes and host computers. The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

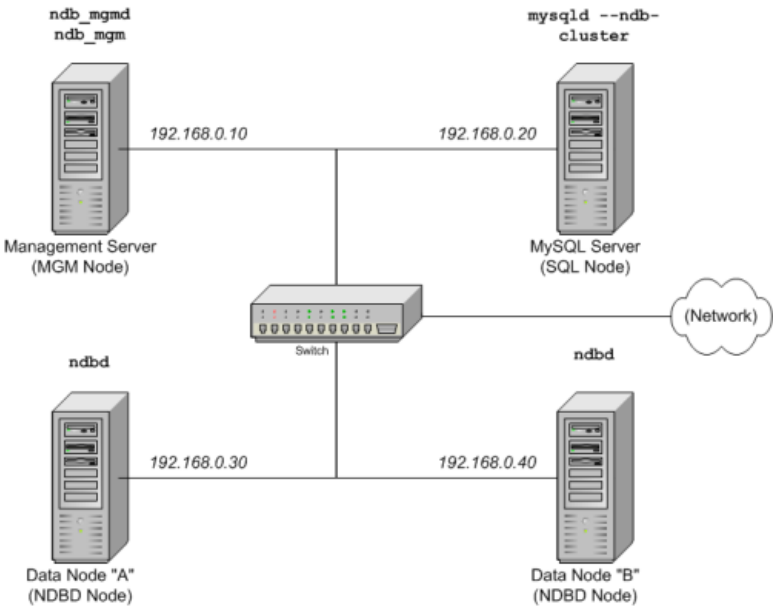
Table 22.4 Network addresses of nodes in example cluster

Node	IP Address
Management node (`mgmd`)	198.51.100.10

Node	IP Address
SQL node (`mysqld`)	198.51.100.20
Data node "A" (`ndbd`)	198.51.100.30
Data node "B" (`ndbd`)	198.51.100.40

This setup is also shown in the following diagram:

Figure 22.4 NDB Cluster Multi-Computer Setup



Network addressing. In the interest of simplicity (and reliability), this *How-To* uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `hosts` file (typically `/etc/hosts` for Linux and other Unix-like operating systems, `C:\WINDOWS\system32\drivers\etc\hosts` on Windows, or your operating system's equivalent) for providing a means to do host lookup if such is available.

Potential hosts file issues. A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc/hosts` during installation. Consider two machines with the host names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```
#  ndb1 /etc/hosts:
127.0.0.1   ndb1.cluster ndb1 localhost.localdomain localhost
```

```
#  ndb2 /etc/hosts:
127.0.0.1   ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' `/etc/hosts` files:

```
#  ndb1 /etc/hosts:
127.0.0.1       localhost
127.0.0.2       ndb1.cluster ndb1
```

```
#  ndb2 /etc/hosts:
```

```
127.0.0.1       localhost
127.0.0.2       ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

Caution

You cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for *all* `config.ini` `HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

Host computer type. Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

Network hardware. Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards *or* all four machines should have 1 Gbps cards.) NDB Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

Important

NDB Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run an NDB Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

Sample data. We use the `world` database which is available for download from the MySQL website (see https://dev.mysql.com/doc/index-other.html). We assume that each machine has sufficient memory for running the operating system, required NDB Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see Chapter 2, *Installing and Upgrading MySQL*. For information about installation of NDB Cluster on Linux and other Unix-like operating systems, see Section 22.2.2, “Installation of NDB Cluster on Linux”. For information about installation of NDB Cluster on Windows operating systems, see Section 22.2.3, “Installing NDB Cluster on Windows”.

For general information about NDB Cluster hardware, software, and networking requirements, see Section 22.1.3, “NDB Cluster Hardware, Software, and Networking Requirements”.

22.2.1 The NDB Cluster Auto-Installer

This section describes the web-based graphical configuration installer included as part of the NDB Cluster distribution. Topics discussed include an overview of the installer and its parts, software and other requirements for running the installer, navigating the GUI, and using the installer to set up and start or stop an NDB Cluster on one or more host computers.

The NDB Cluster Auto-Installer is made up of two components. The front end is a GUI client implemented as a Web page that loads and runs in a standard Web browser such as Firefox or

Microsoft Internet Explorer. The back end is a server process (`ndb_setup.py`) that runs on the local machine or on another host to which you have access.

These two components (client and server) communicate with each other using standard HTTP requests and responses. The back end can manage NDB Cluster software programs on any host where the back end user has granted access. If the NDB Cluster software is on a different host, the back end relies on SSH for access, using the Paramiko library for executing commands remotely (see Section 22.2.1.1, “NDB Cluster Auto-Installer Requirements”).

22.2.1.1 NDB Cluster Auto-Installer Requirements

This section provides information on supported operating platforms and software, required software, and other prerequisites for running the NDB Cluster Auto-Installer.

Supported platforms. The NDB Cluster Auto-Installer is available with NDB 8.0 distributions for recent versions of Linux, Windows, Solaris, and MacOS X. For more detailed information about platform support for NDB Cluster and the NDB Cluster Auto-Installer, see https://www.mysql.com/support/supportedplatforms/cluster.html.

Supported web browsers. The web-based installer is supported with recent versions of Firefox and Microsoft Internet Explorer. It should also work with recent versions of Opera, Safari, and Chrome, although we have not thoroughly tested for compability with these browsers.

Required software—setup host. The following software must be installed on the host where the Auto-Installer is run:

- **Python 2.6 or higher.** The Auto-Installer requires the Python interpreter and standard libraries. If these are not already installed on the system, you may be able to add them using the system's package manager. Otherwise, you can download them from http://python.org/download/.
- **Paramiko 2 or higher.** This is required to communicate with remote hosts using SSH. You can download it from http://www.lag.net/paramiko/. Paramiko may also be available from your system's package manager.
- **Pycrypto version 1.9 or higher.** This cryptography module is required by Paramiko, and can be iunstalled using `pip install cryptography`. If `pip` is not installed, and the module is not available using your system's package manage, you can download it from https://www.dlitz.net/software/pycrypto/.

All of the software in the preceding list is included in the Windows version of the configuration tool, and does not need to be installed separately.

The Paramiko and Pycrypto libraries are required only if you intend to deploy NDB Cluster nodes on remote hosts, and are not needed if all nodes are on the same host where the installer is run.

Required software—remote hosts. The only software required for remote hosts where you wish to deploy NDB Cluster nodes is the SSH server, which is usually installed by default on Linux and Solaris systems. Several alternatives are available for Windows; for an overview of these, see http://en.wikipedia.org/wiki/Comparison_of_SSH_servers.

An additional requirement when using multiple hosts is that it is possible to authenticate to any of the remote hosts using SSH and the proper keys or user credentials, as discussed in the next few paragraphs:

Authentication and security. Three basic security or authentication mechanisms for remote access are available to the Auto-Installer, which we list and describe here:

- **SSH.** A secure shell connection is used to enable the back end to perform actions on remote hosts. For this reason, an SSH server must be running on the remote host. In addition, the operating system user running the installer must have access to the remote server, either with a user name and password, or by using public and private keys.

Important

You should never use the system `root` account for remote access, as this is extremely insecure. In addition, `mysqld` cannot normally be started by system `root`. For these and other reasons, you should provide SSH credentials for a regular user account on the target system, and not for system `root`. For more information about this issue, see Section 6.1.5, "How to Run MySQL as a Normal User".

- **HTTPS.** Remote communication between the Web browser front end and the back end is not encrypted by default, which means that information such as the user's SSH password is transmitted in clear text that is readable to anyone. For communication from a remote client to be encrypted, the back end must have a certificate, and the front end must communicate with the back end using HTTPS rather than HTTP. Enabling HTTPS is accomplished most easily through issuing a self-signed certificate. Once the certificate is issued, you must make sure that it is used. You can do this by starting `ndb_setup.py` from the command line with the `--use-https` (`-S`) and `--cert-file` (`-c`) options.

  A sample certificate file `cfg.pem` is included and is used by default. This file is located in the `mcc` directory under the installation share directory; on Linux, the full path to the file is normally `/usr/share/mysql/mcc/cfg.pem`. On Windows systems, this is usually `C:\Program Files\MySQL\MySQL Server 8.0\share\mcc\cfg.pem`. Letting the default be used means that, for testing purposes, you can simply start the installer with the `-S` option to use an HTTPS connection between the browser and the back end.

  The Auto-Installer saves the configuration file for a given cluster `mycluster01` as `mycluster01.mcc` in the home directory of the user invoking the `ndb_setup.py` executable. This file is encrypted with a passphrase supplied by the user (using Fernet); because HTTP transmits the passphrase in the clear, *it is strongly recommended that you always use an HTTPS connection to access the Auto-Installer on a remote host*.

- **Certificate-based authentication.** The back end `ndb_setup.py` process can execute commands on the local host as well as remote hosts. This means that anyone connecting to the back end can take charge of how commands are executed. To reject unwanted connections to the back end, a certificate may be required for authentication of the client. In this case, a certificate must be issued by the user, installed in the browser, and made available to the back end for authentication purposes. You can enact this requirement (together with or in place of password or key authentication) by starting `ndb_setup.py` with the `--ca-certs-file` (`-a`) option.

There is no need or requirement for secure authentication when the client browser is running on the same host as the Auto-Installer back end.

See also Section 22.5.12, "NDB Cluster Security Issues", which discusses security considerations to take into account when deploying NDB Cluster, as well as Chapter 6, *Security*, for more general MySQL security information.

22.2.1.2 Using the NDB Cluster Auto-Installer

The NDB Cluster Auto-Installer interface is made up of several pages, each corresponding to a step in the process used to configure and deploy an NDB Cluster. These pages are listed here, in order:

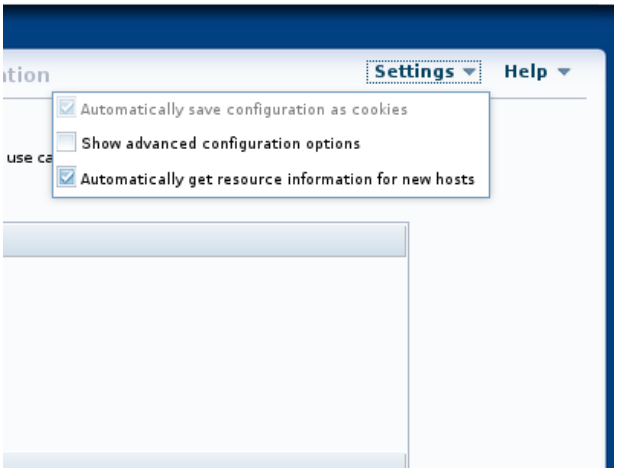
- **Welcome**: Begin using the Auto-Installer by choosing either to configure a new NDB Cluster, or to continue configuring an existing one.
- **Define Cluster**: Set basic information about the cluster as a whole, such as name, hosts, and load type. Here you can also set the SSH authentication type for accessing remote hosts, if needed.
- **Define Hosts**: Identify the hosts where you intend to run NDB Cluster processes.
- **Define Processes**: Assign one or more processes of a given type or types to each cluster host.

- **Define Parameters**: Set configuration attributes for processes or types of processes.
- **Deploy Configuration**: Deploy the cluster with the configuration set previously; start and stop the deployed cluster.

NDB Cluster Installer Settings and Help Menus

These menus are shown on all screens except for the **Welcome** screen. They provide access to installer settings and information. The **Settings** menu is shown here in more detail:

Figure 22.5 NDB Cluster Auto-Installer Settings menu



The **Settings** menu has the following entries:

- **Automatically save configuration as cookies**: Save your configuration information—such as host names, process data, and parameter values—as a cookie in the browser. When this option is chosen, all information except any SSH password is saved. This means that you can quit and restart the browser, and continue working on the same configuration from where you left off at the end of the previous session. This option is enabled by default.

  The SSH password is never saved; if you use one, you must supply it at the beginning of each new session.

- **Show advanced configuration options**: Shows by default advanced configuration parameters where available.

  Once set, the advanced parameters continue to be used in the configuration file until they are explicitly changed or reset. This is regardless of whether the advanced parameters are currently visible in the installer; in other words, disabling the menu item does not reset the values of any of these parameters.

  You can also toggle the display of advanced parameters for individual processes on the **Define Parameters** screen.

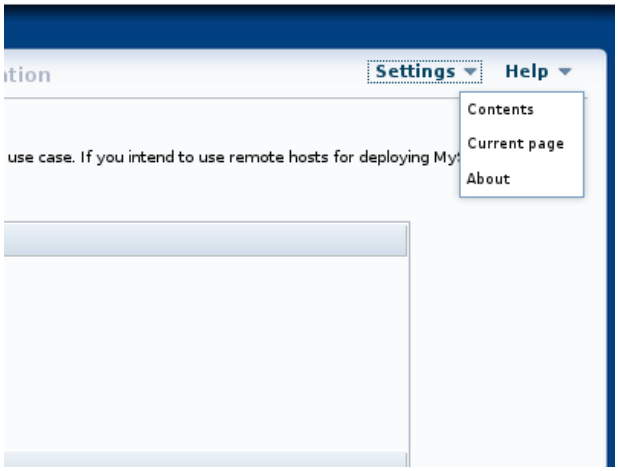
  This option is disabled by default.

- **Automatically get resource information for new hosts**: Query new hosts automatically for hardware resource information to pre-populate a number of configuration options and values. In this case, the suggested values are not mandatory, but they are used unless explicitly changed using the appropriate editing options in the installer.

  This option is enabled by default.

The installer **Help** menu is shown here:

Figure 22.6 NDB Cluster Auto-Installer Help menu



The **Help** menu provides several options, described in the following list:

- **Contents**: Show the built-in user guide. This is opened in a separate browser window, so that it can be used simultaneously with the installer without interrupting workflow.
- **Current page**: Open the built-in user guide to the section describing the page currently displayed in the installer.
- **About**: open a dialog displaying the installer name and the version number of the NDB Cluster distribution with which it was supplied.

The Auto-Installer also provides context-sensitive help in the form of tooltips for most input widgets.

In addition, the names of most NDB configuration parameters are linked to their descriptions in the online documentation. The documentation is displayed in a separate browser window.

The next section discusses starting the Auto-Installer. The sections immediately following it describe in greater detail the purpose and function of each of these pages in the order listed previously.

Starting the NDB Cluster Auto-Installer

The Auto-Installer is provided together with the NDB Cluster software. Separate RPM and `.deb` packages containing only the Auto-Installer are also available for many Linux distributions. (See Section 22.2, “NDB Cluster Installation”.)

The present section explains how to start the installer. You can do by invoking the `ndb_setup.py` executable.

User and privileges

You should run the `ndb_setup.py` as a normal user; no special privileges are needed to do so. You should *not* run this program as the `mysql` user, or using the system `root` or Administrator account; doing so may cause the installation to fail.

`ndb_setup.py` is found in the `bin` within the NDB Cluster installation directory; a typical location might be `/usr/local/mysql/bin` on a Linux system or `C:\Program Files\MySQL\MySQL Server 8.0\bin` on a Windows system. This can vary according to where the NDB Cluster software is installed on your system, and the installation method.

On Windows, you can also start the installer by running `setup.bat` in the NDB Cluster installation directory. When invoked from the command line, this batch file accepts the same options as `ndb_setup.py`.

`ndb_setup.py` can be started with any of several options that affect its operation, but it is usually sufficient to allow the default settings be used, in which case you can start `ndb_setup.py` by either of the following two methods:

1. Navigate to the NDB Cluster `bin` directory in a terminal and invoke it from the command line, without any additional arguments or options, like this:

   ```
   shell> ndb_setup.py
   Running out of install dir: /usr/local/mysql/bin
   Starting web server on port 8081
   URL is https://localhost:8081/welcome.html
   deathkey=627876
   Press CTRL+C to stop web server.
   The application should now be running in your browser.
   (Alternatively you can navigate to https://localhost:8081/welcome.html to start it)
   ```

   This works regardless of operating platform.

2. Navigate to the NDB Cluster `bin` directory in a file browser (such as Windows Explorer on Windows, or Konqueror, Dolphin, or Nautilus on Linux) and activate (usually by double-clicking) the **ndb_setup.py** file icon. This works on Windows, and should work with most common Linux desktops as well.

   On Windows, you can also navigate to the NDB Cluster installation directory and activate the **setup.bat** file icon.

In either case, once `ndb_setup.py` is invoked, the Auto-Installer's **Welcome** screen should open in the system's default web browser. If not, you should be able to open the page `http://localhost:8081/welcome.html` or `https://localhost:8081/welcome.html` manually in the browser.

In some cases, you may wish to use non-default settings for the installer, such as specifying HTTPS for connections, or a different port for the Auto-Installer's included web server to run on, in which case you must invoke `ndb_setup.py` with one or more startup options with values overriding the necessary defaults. The same startup options can be used on Windows systems with the `setup.bat` file supplied for such platforms in the NDB Cluster software distribution. This can be done using the command line, but if you want or need to start the installer from a desktop or file browser while employing one or more of these options, it is also possible to create a script or batch file containing the proper invocation, then to double-click its file icon in the file browser to start the installer. (On Linux systems, you might also need to make the script file executable first.) If you plan to use the Auto-Installer from a remote host, you should start using the `-S` option. For information about this and other advanced startup options for the NDB Cluster Auto-Installer, see Section 22.4.26, “ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster”.

NDB Cluster Auto-Installer Welcome Screen

The **Welcome** screen is loaded in the default browser when `ndb_setup.py` is invoked. The first time the Auto-Installer is run (or if for some other reason there are no existing configurations), this screen appears as shown here:

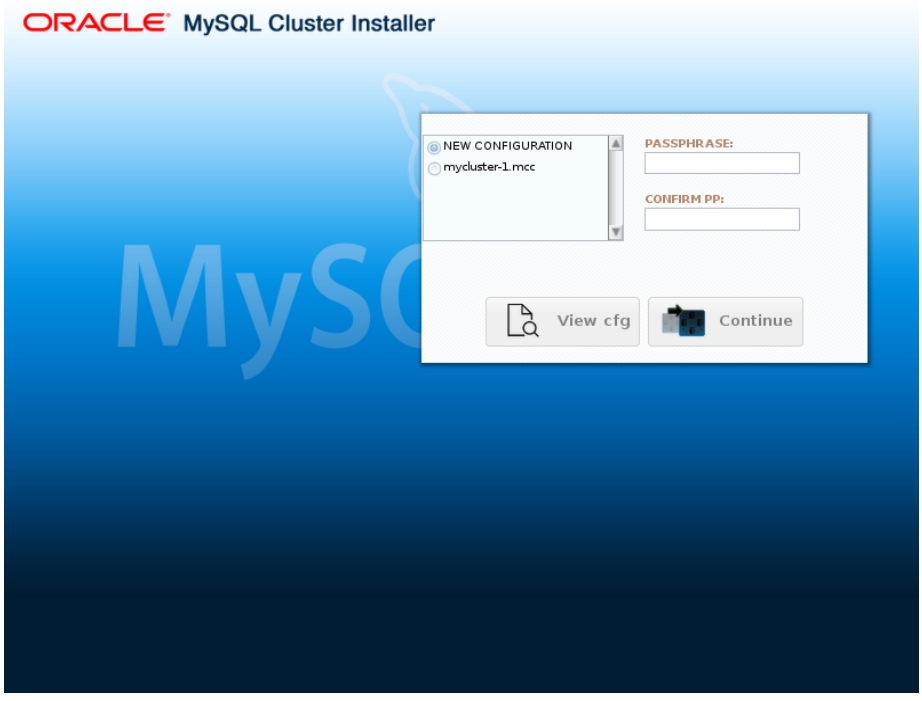
Figure 22.7 The NDB Cluster Auto-Installer Welcome screen, first run

In this case, the only choice of cluster listed is for configuration of a new cluster, and both the **View Cfg** and **Continue** buttons are inactive.

To create a new configuration, enter and confirm a passphrase in the text boxes provided. When this has been done, you can click **Continue** to proceed to the **Define Cluster** screen where you can assign a name to the new cluster.

If you have previously created one or more clusters with the Auto-Installer, they are listed by name. This example shows an existing cluster named `mycluster-1`:

Figure 22.8 The NDB Cluster Auto-Installer Welcome screen, with previously created cluster mycluster-1

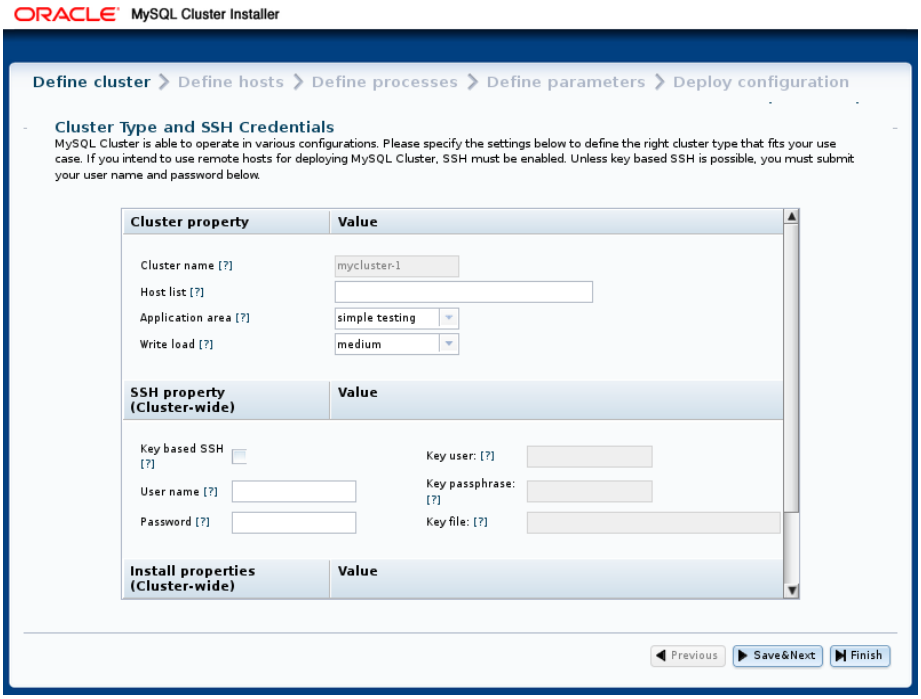


To view the configuration for and work with a given cluster, select the radiobutton next to its name in the list, then enter and confirm the passphrase that was used to create it. When you have done this correctly, you can click **View Cfg** to view and edit this cluster's configuration.

NDB Cluster Auto-Installer Define Cluster Screen

The **Define Cluster** screen is appears following the **Welcome** screen, and is used for setting general properties of the cluster. The layout of the **Define Cluster** screen is shown here:

Figure 22.9 The NDB Cluster Auto-Installer Define Cluster screen



This screen and subsequent screens also include **Settings** and **Help** menus which are described later in this section; see NDB Cluster Installer Settings and Help Menus.

The **Define Cluster** screen allows you to set three sorts of properties for the cluster: cluster properties, SSH properties, and installation properties.

Cluster properties that can be set on this screen are listed here:

- **Cluster name**: A name that identifies the cluster; in this example, this is `mycluster-1`. The name is set on the previous screen and cannot be changed here.
- **Host list**: A comma-delimited list of one or more hosts where cluster processes should run. By default, this is `127.0.0.1`. If you add remote hosts to the list, you must be able to connect to them using the credentials supplied as SSH properties.
- **Application type**: Choose one of the following:
  1. **Simple testing**: Minimal resource usage for small-scale testing. This the default. *Not intended for production environments*.
  2. **Web**: Maximize performance for the given hardware.
  3. **Real-time**: Maximize performance while maximizing sensitivity to timeouts in order to minimize the time needed to detect failed cluster processes.
- **Write load**: Choose a level for the anticipated number of writes for the cluster as a whole. You can choose any one of the following levels:

1. **Low**: The expected load includes fewer than 100 write transactions for second.
2. **Medium**: The expected load includes 100 to 1000 write transactions per second; this is the default.
3. **High**: The expected load includes more than 1000 write transactions per second.

SSH properties are described in the following list:

- **Key-Based SSH**: Check this box to use key-enabled login to the remote host. If checked, the key user and passphrase must also be supplied; otherwise, a user and password for a remote login account are needed.
- **User**: Name of user with remote login access.
- **Password**: Password for remote user.
- **Key user**: Name of the user for whom the key is valid, if not the same as the operating system user.
- **Key passphrase**: Passphrase for the key, if required.
- **Key file**: Path to the key file. The default is `~/.ssh/id_rsa`.

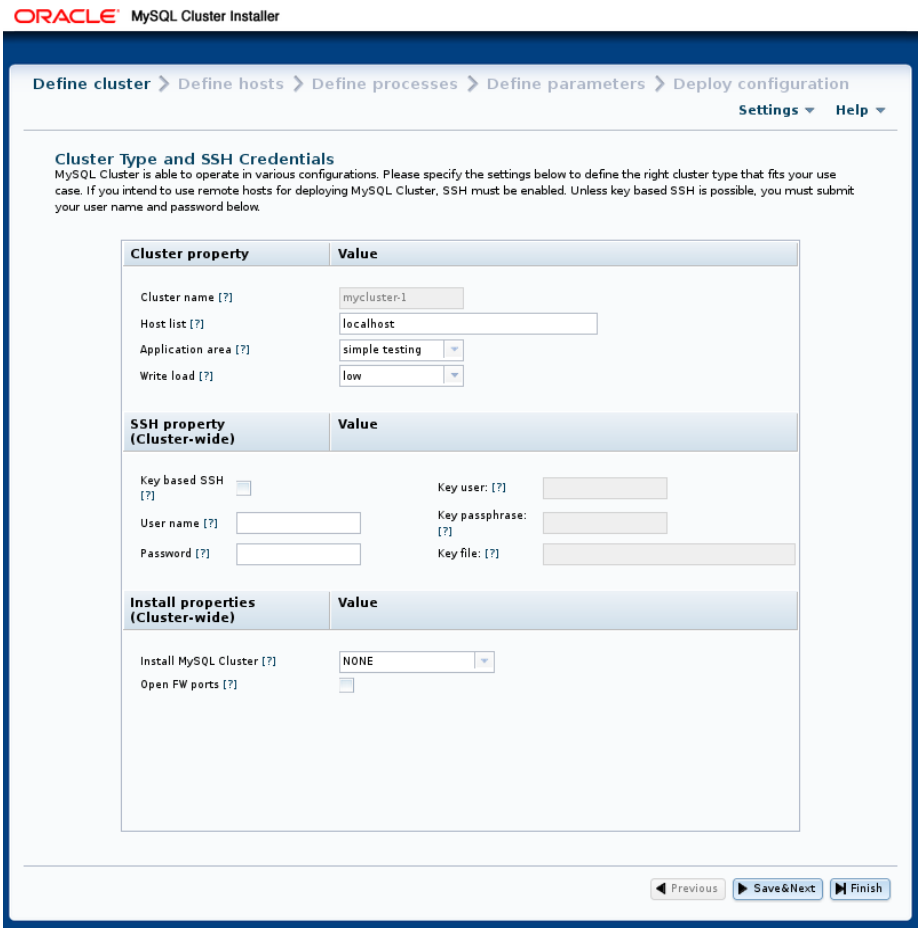
The SSH properties set on this page apply to all hosts in the cluster. They can be overridden for a given host by editing that hosts's properties on the **Define Hosts** screen.

Two installation properties can also be set on this screen:

- **Install MySQL Cluster**: This setting determines the source from which the Auto-Installer installs NDB Cluster software, if any, on the cluster hosts. Possible values and their effects are listed here:
  1. `DOCKER`: Try to install the MySQL Cluster Docker image from `https://hub.docker.com/r/mysql/mysql-cluster/` on each host
  2. `REPO`: Try to install the NDB Cluster software from the MySQL Repositories on each host
  3. `BOTH`: Try to install either the Docker image or the software from the repository on each host, giving preference to the repository
  4. `NONE`: Do not install the NDB Cluster software on the hosts; this is the default
- **Open FW Ports**: Check this checkbox to have the installer attempt to open ports required by NDB CLuster processes on all hosts.

The next figure shows the **Define Cluster** page with settings for a small test cluster with all nodes running on `localhost`:

Figure 22.10 The NDB Cluster Auto-Installer Define Cluster screen, with settings for a test cluster



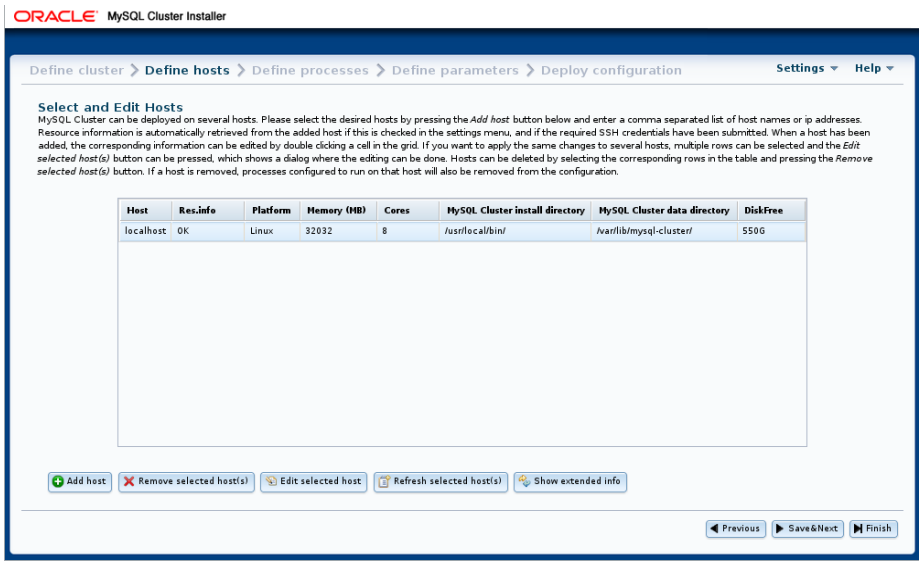
After making the desired settings, you can save them to the configuration file and proceed to the **Define Hosts** screen by clicking the **Save & Next** button.

If you exit the installer without saving, no changes are made to the configuration file.

NDB Cluster Auto-Installer Define Hosts Screen

The **Define Hosts** screen, shown here, provides a means of viewing and specifying several key properties of each cluster host:

Figure 22.11 NDB Cluster Define Hosts screen, start



Properties shown include the following:

- **Host**: Name or IP address of this host
- **Res.info**: Shows `OK` if the installer was able to retrieve requested resource information from this host
- **Platform**: Operating system or platform
- **Memory (MB)**: Amount of RAM on this host
- **Cores**: Number of CPU cores available on this host
- **MySQL Cluster install directory**: Path to directory where the NDB Cluster software is installed on this host; defaults to `/usr/local/bin`
- **MySQL Cluster data directory**: Path to directory used for data by NDB Cluster processes on this host; defaults to `/var/lib/mysql-cluster`.
- **DiskFree**: Free disk space in bytes

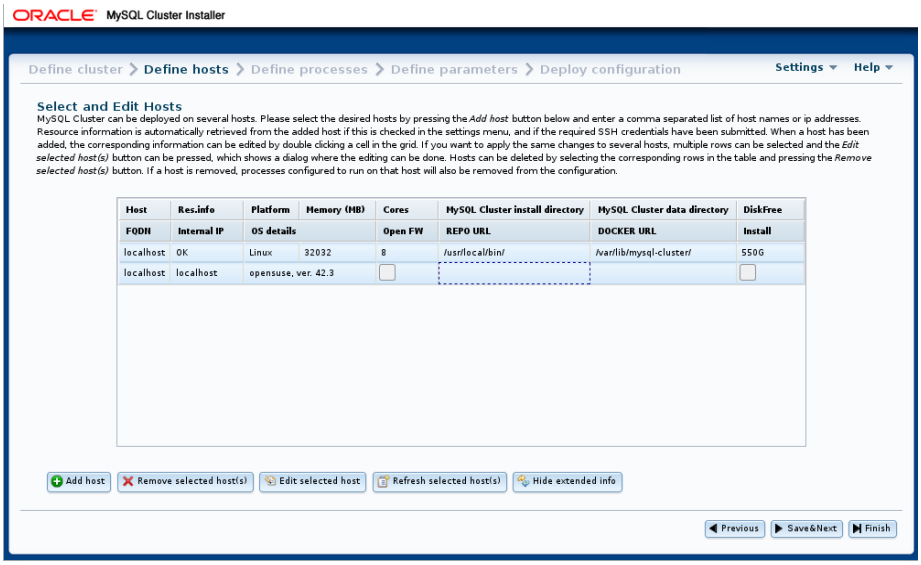
  For hosts with multiple disks, only the space available on the disk used for the data directory is shown.

This screen also provides an extended view for each host that includes the following properties:

- **FDQN**: This host's fully qualified domain name, used by the installer to connect with it, distribute configuration information to it, and start and stop cluster processes on it.
- **Internal IP**: The IP address used for communication with cluster processes running on this host by processes running elsewhere.
- **OS Details**: Detailed operating system name and version information.
- **Open FW**: If this checkbox is enabled, the installer attempts to open ports in the host's firewall needed by cluster processes.
- **REPO URL**: URL for MySQL NDB Cluster repository
- **DOCKER URL**: URL for MySQL NDB CLuster Docker images; for NDB 8.0, this is `mysql/mysql-cluster:8.0`.
- **Install**: If this checkbox is enabled, the Auto-Installer attempts to install the NDB Cluster software on this host

The extended view is shown here:

Figure 22.12 NDB Cluster Define Hosts screen, extended host info view



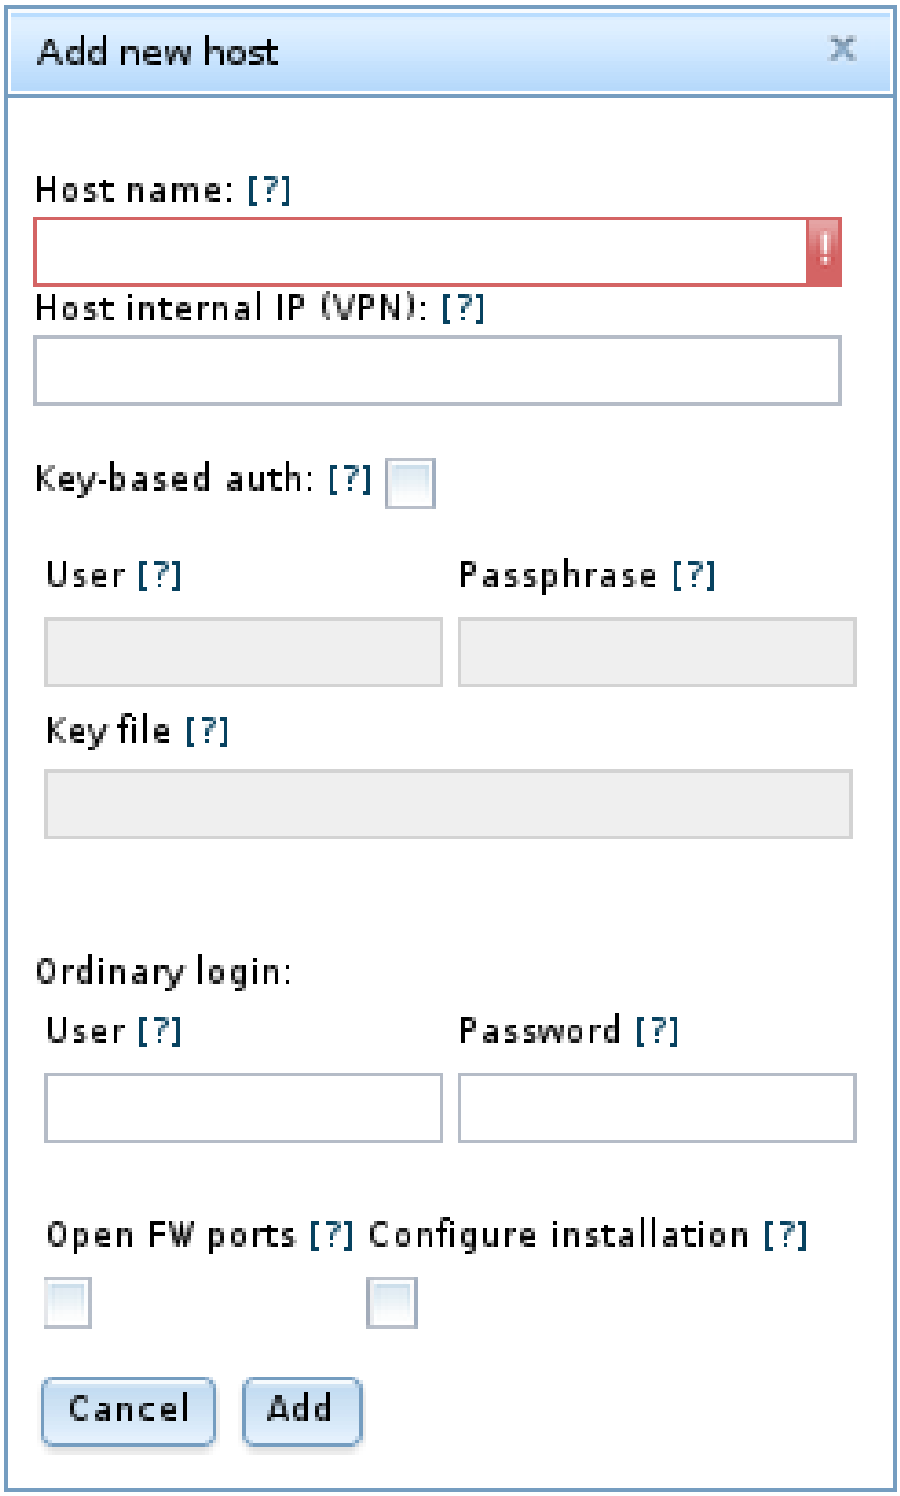
All cells in the display are editable, with the exceptions of those in the **Host**, **Res.info**, and **FQDN** columns.

Be aware that it may take some time for information to be retrieved from remote hosts. Fields for which no value could be retrieved are indicated with an ellipsis (...). You can retry the fetching of resource information from one or more hosts by selecting the hosts in the list and then clicking the **Refresh selected host(s)** button.

Adding and Removing Hosts

You can add one or more hosts by clicking the **Add Host** button and entering the required properties where indicated in the **Add new host** dialog, shown here:

Figure 22.13 NDB Cluster Add Host dialog



This dialog includes the following fields:

- **Host name**: A comma-separated list of one or more host names, IP addresses, or both. These must be accessible from the host where the Auto-Installer is running.
- **Host internal IP (VPN)**: If you are setting up the cluster to run on a VPN or other internal network, enter the IP address or addresses used for contact by cluster nodes on other hosts.

- **Key-based auth**: If checked, enables key-based authentication. You can enter any additional needed information in the **User**, **Passphrase**, and **Key file** fields.
- **Ordinary login**: If accessing this host using a password-based login, enter the appropriate information in the **User** and **Password** fields.
- **Open FW ports**: Selecting this checkbox allows the installer try opening any ports needed by cluster processes in this host's firewall.
- **Configure installation**: Checking this allows the Auto-Install to attempt to set up the NDB Cluster software on this host.

To save the new host and its properties, click **Add**. If you wish to cancel without saving any changes, click **Cancel** instead.

Similarly, you can remove one or more hosts using the button labelled **Remove selected host(s)**. *When you remove a host, any process which was configured for that host is also removed*.

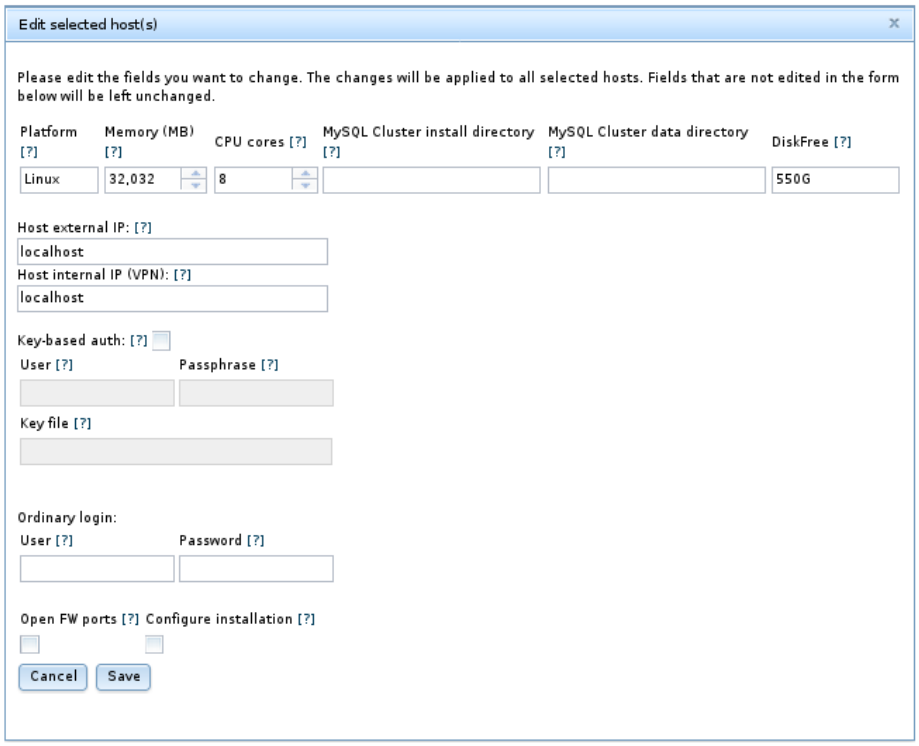
Warning

Remove selected host(s) acts immediately. There is no confirmation dialog. If you remove a host in error, you must re-enter its name and properties manually using **Add host**.

If the SSH user credentials on the *Define Cluster* screen are changed, the Auto-Installer attempts to refresh the resource information from any hosts for which information is missing.

You can edit the host's platform name, hardware resource information, installation directory, and data directory by clicking the corresponding cell in the grid, by selecting one or more hosts and clicking the button labelled **Edit selected host(s)**. This causes a dialog box to appear, in which these fields can be edited, as shown here:

Figure 22.14 NDB Cluster Auto-Installer Edit Hosts dialog



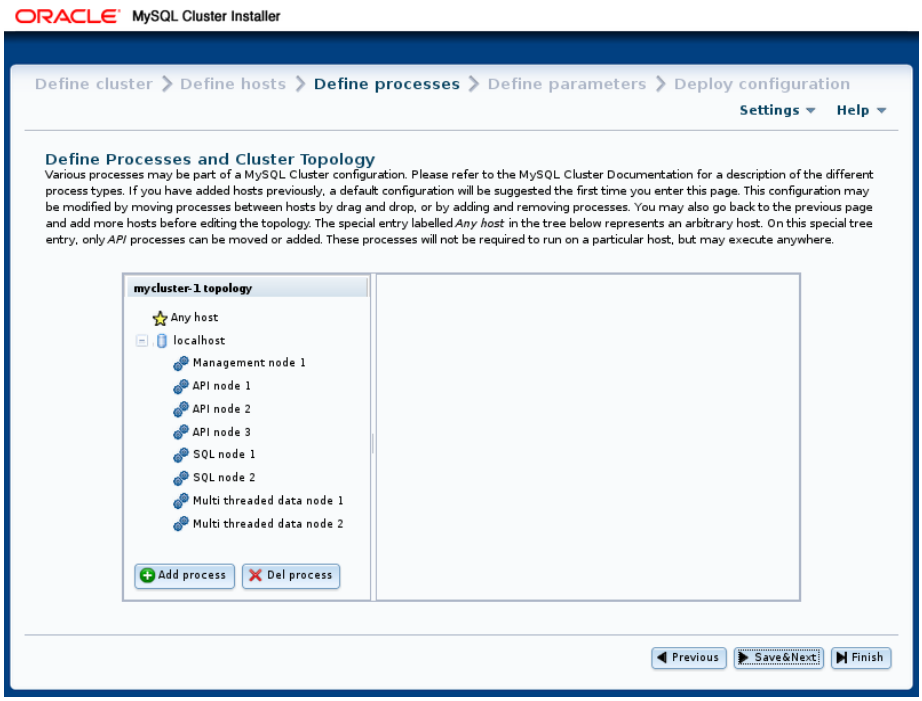
When more than one host is selected, any edited values are applied to all selected hosts.

Once you have entered all desired host information, you can use the **Save & Next** button to save the information to the cluster's configuration file and proceed to the **Define Processes** screen, where you can set up NDB Cluster processes on one or more hosts.

NDB Cluster Auto-Installer Define Processes Screen

The **Define Processes** screen, shown here, provides a way to assign NDB Cluster processes (nodes) to cluster hosts:

Figure 22.15 NDB Cluster Auto-Installer Define Processes dialog



This screen contains a process tree showing cluster hosts and processes set up to run on each one, as well as a panel which displays information about the item currently selected in the tree.

When this screen is accessed for the first time for a given cluster, a default set of processes is defined for you, based on the number of hosts. If you later return to the **Define Hosts** screen, remove all hosts, and add new hosts, this also causes a new default set of processes to be defined.

NDB Cluster processes are of the types described in this list:

- **Management node.** Performs administrative tasks such as stopping individual data nodes, querying node and cluster status, and making backups. Executable: `ndb_mgmd`.
- **Single-threaded data node.** Stores data and executes queries. Executable: `ndbd`.
- **Multi threaded data node.** Stores data and executes queries with multiple worker threads executing in parallel. Executable: `ndbmtd`.
- **SQL node.** MySQL server for executing SQL queries against `NDB`. Executable: `mysqld`.
- **API node.** A client accessing data in `NDB` by means of the NDB API or other low-level client API, rather than by using SQL. See MySQL NDB Cluster API Developer Guide, for more information.

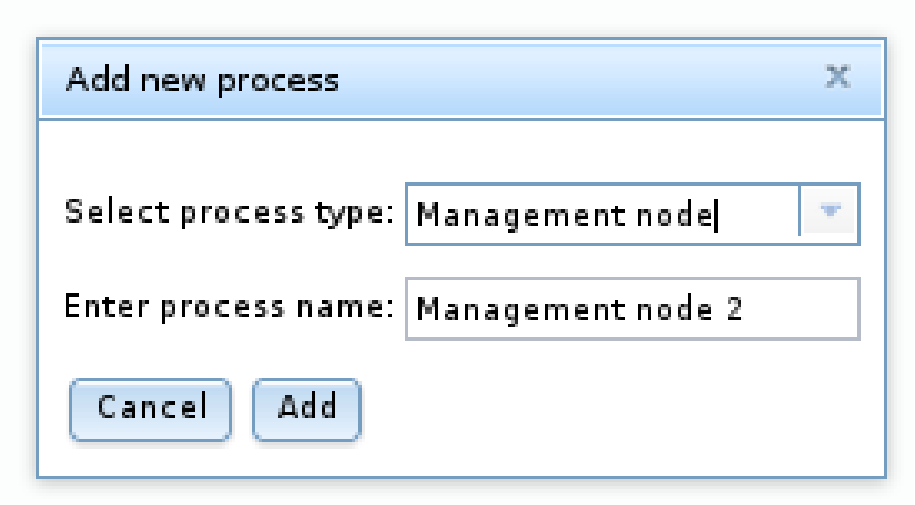
For more information about process (node) types, see Section 22.1.1, “NDB Cluster Core Concepts”.

Processes shown in the tree are numbered sequentially by type, for each host—for example, `SQL node 1`, `SQL node 2`, and so on—to simplify identification.

Each management node, data node, or SQL process must be assigned to a specific host, and is not allowed to run on any other host. An API node *may* be assigned to a single host, but this is not required. Instead, you can assign it to the special **Any host** entry which the tree also contains in addition to any other hosts, and which acts as a placeholder for processes that are allowed to run on any host. *Only API processes may use this **Any host** entry*.

Adding processes. To add a new process to a given host, either right-click that host's entry in the tree, then select the **Add process** popup when it appears, or select a host in the process tree, and press the **Add process** button below the process tree. Performing either of these actions opens the add process dialog, as shown here:

Figure 22.16 NDB Cluster Auto-Installer Add Process Dialog



Here you can select from among the available process types described earlier this section; you can also enter an arbitrary process name to take the place of the suggested value, if desired.

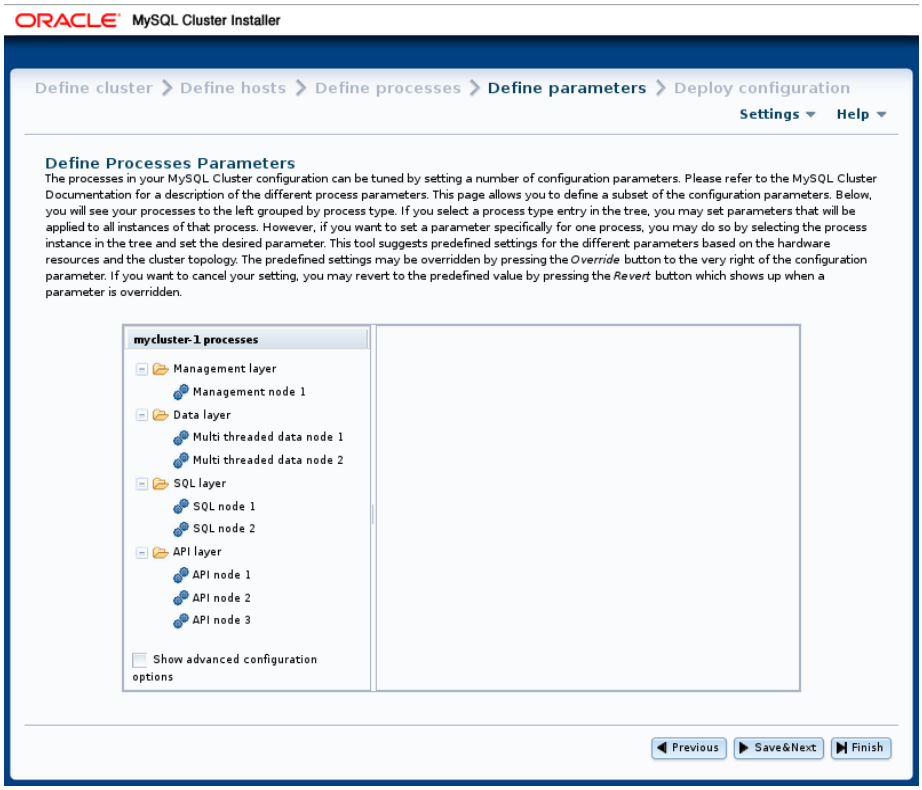
Removing processes. To delete a process, select that process in the tree and use the **Del process** button.

When you select a process in the process tree, information about that process is displayed in the information panel, where you can change the process name and possibly its type. You can change a multi-threaded data node (`ndbmtd`) to a single-threaded data node (`ndbd`), or the reverse, only; no other process type changes are allowed. *If you want to make a change between any other process types, you must delete the original process first, then add a new process of the desired type*.

NDB Cluster Auto-Installer Define Parameters Screen

Like the **Define Processes** screen, this screen includes a process tree; the **Define Parameters** process tree is organized by process or node type, in groups labelled **Management Layer**, **Data Layer**, **SQL Layer**, and **API Layer**. An information panel displays information regarding the item currently selected. The **Define Attributes** screen is shown here:

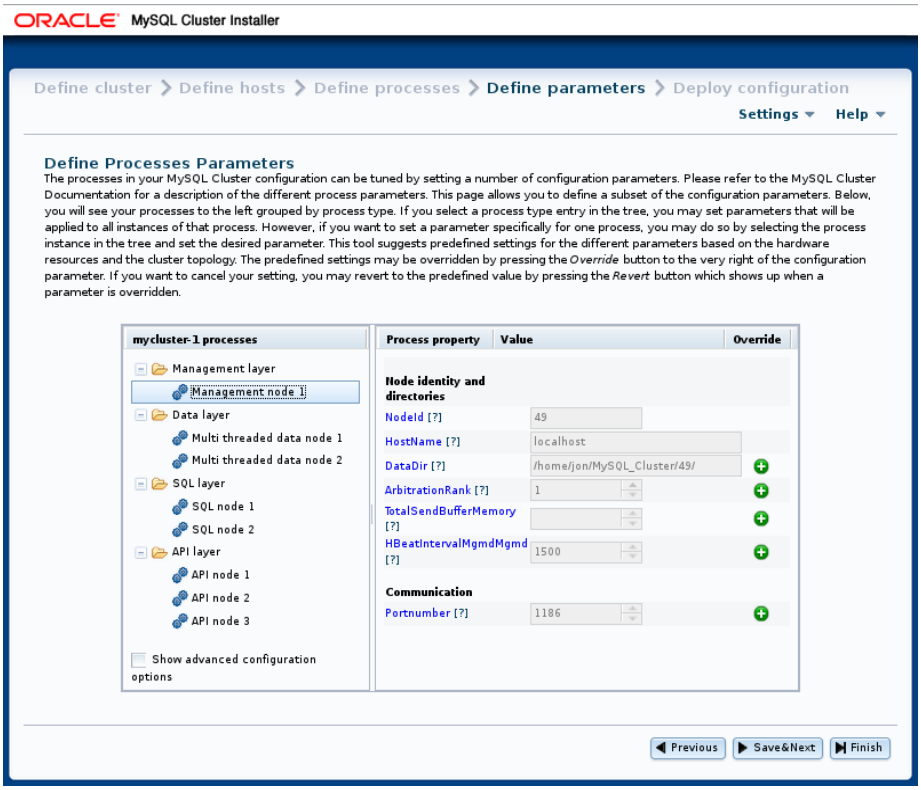
Figure 22.17 NDB Cluster Auto-Installer Define Parameters screen



The checkbox labelled **Show advanced configuration**, when checked, makes advanced options for data node and SQL node processes visible in the information pane. These options are set and used whether or not they are visible. You can also enable this behavior globally by checking **Show advanced configuration options** under **Settings** (see NDB Cluster Installer Settings and Help Menus).

You can edit attributes for a single process by selecting that process from the tree, or for all processes of the same type in the cluster by selecting one of the **Layer** folders. A per-process value set for a given attribute overrides any per-group setting for that attribute that would otherwise apply to the process in question. An example of such an information panel (for an SQL process) is shown here:

Figure 22.18 Define Parameters—Process Attributes



Attributes whose values can be overridden are shown in the information panel with a button bearing a plus sign. This **+** button activates an input widget for the attribute, enabling you to change its value. When the value has been overridden, this button changes into a button showing an **X**. The **X** button undoes any changes made to a given attribute, which immediately reverts to the predefined value.

All configuration attributes have predefined values calculated by the installer, based such factors as host name, node ID, node type, and so on. In most cases, these values may be left as they are. If you are not familiar with it already, it is highly recommended that you read the applicable documentation before making changes to any of the attribute values. To make finding this information easier, each attribute name shown in the information panel is linked to its description in the online NDB Cluster documentation.

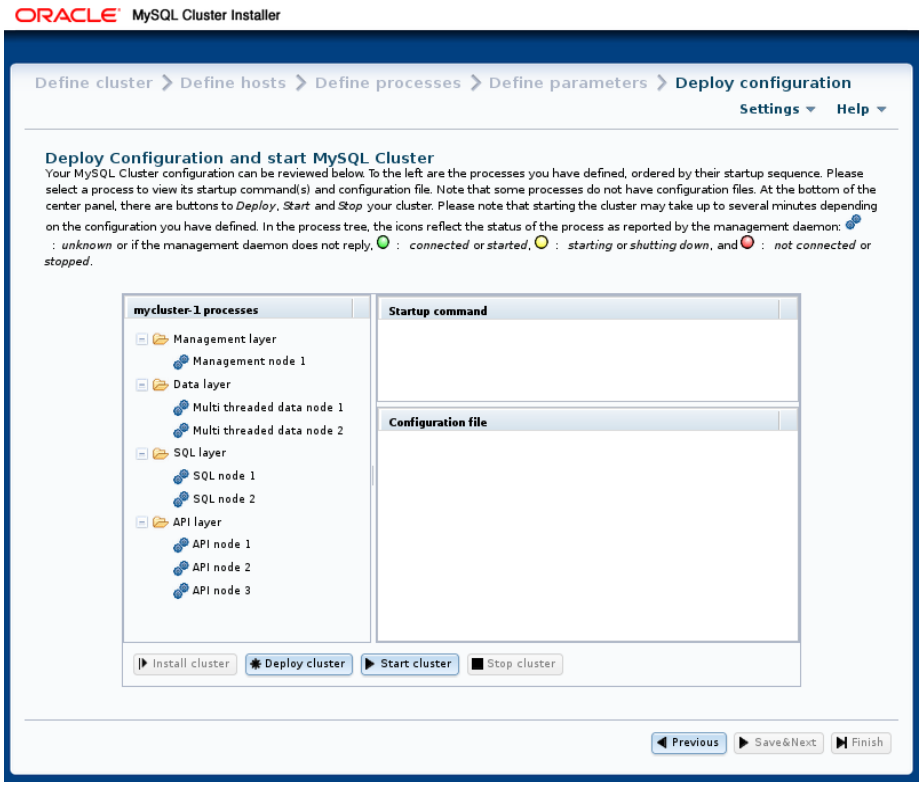
NDB Cluster Auto-Installer Deploy Configuration Screen

This screen allows you to perform the following tasks:

- Review process startup commands and configuration files to be applied
- Distribute configuration files by creating any necessary files and directories on all cluster hosts—that is, *deploy* the cluster as presently configured
- Start and stop the cluster

The **Deploy Configuration** screen is shown here:

Figure 22.19 NDB Cluster Auto-Installer Deploy Configuration screen



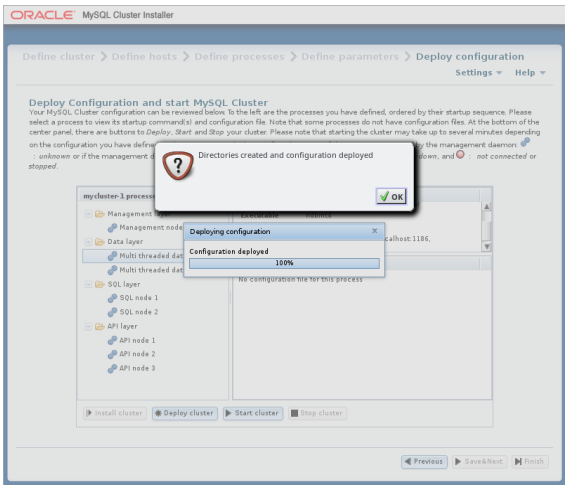
Like the **Define Parameters** screen, this screen features a process tree which is organized by process type. Next to each process in the tree is a status icon indicating the current status of the process: connected (`CONNECTED`), starting (`STARTING`), running (`STARTED`), stopping (`STOPPING`), or disconnected (`NO_CONTACT`). The icon shows green if the process is connected or running; yellow if it is starting or stopping; red if the process is stopped or cannot be contacted by the management server.

This screen also contains two information panels, one showing the startup command or commands needed to start the selected process. (For some processes, more than one command may be required —for example, if initialization is necessary.) The other panel shows the contents of the configuration file, if any, for the given process.

This screen also contains four buttons, labelled as and performing the functions described in the following list:

- **Install cluster**: Nonfunctional in this release; implementation intended for a future release.
- **Deploy cluster**: Verify that the configuration is valid. Create any directories required on the cluster hosts, and distribute the configuration files onto the hosts. A progress bar shows how far the deployment has proceeded, as shown here, and a dialog is pisplayed when the deployment has completed, as shown here:

Figure 22.20 Cluster Deployment Process



- **Start cluster**: The cluster is deployed as with **Deploy cluster**, after which all cluster processes are started in the correct order.

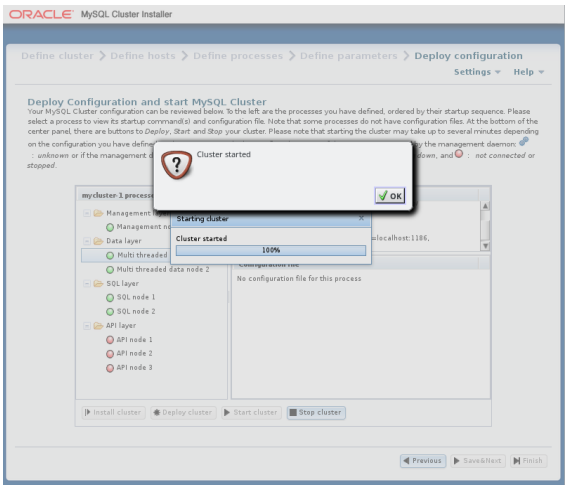
  Starting these processes may take some time. If the estimated time to completion is too large, the installer provides an opportunity to cancel or to continue of the startup procedure. A progress bar indicates the current status of the startup procedure, as shown here:

Figure 22.21 Cluster Startup Process with Progress Bar

  The process status icons next to the items shown in the process tree also update with the status of each process.

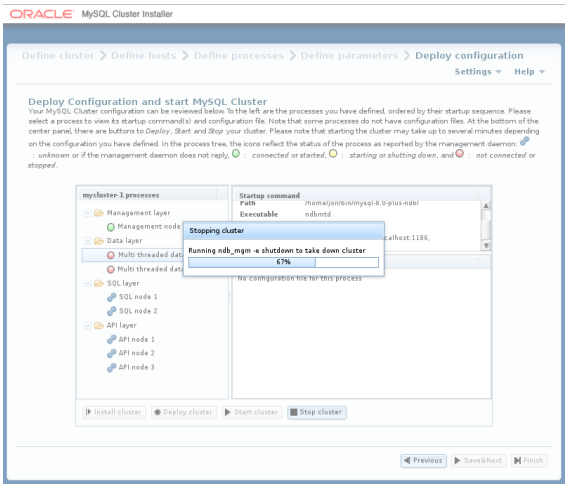
  A confirmation dialog is shown when the startup process has completed, as shown here:

Figure 22.22 Cluster Startup, Process Completed Dialog



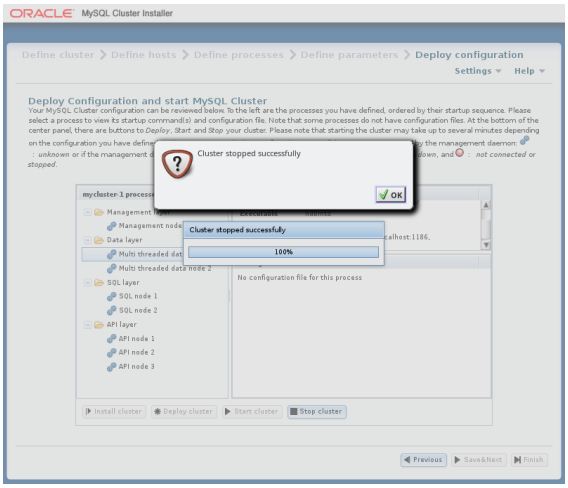
- **Stop cluster**: After the cluster has been started, you can stop it using this. As with starting the cluster, cluster shutdown is not instantaneous, and may require some time complete. A progress bar, similar to that displayed during cluster startup, shows the approximate current status of the cluster shutdown procedure, as do the process status icons adjoining the process tree. The progress bar is shown here:

Figure 22.23 Cluster Shutdown Process, with Progress Bar



A confirmation dialog indicates when the shutdown process is complete:

Figure 22.24 Cluster Shutdown, Process Completed Dialog



The Auto-Installer generates a `config.ini` file containing NDB node parameters for each management node, as well as a `my.cnf` file containing the appropriate options for each `mysqld` process in the cluster. No configuration files are created for data nodes or API nodes.

22.2.2 Installation of NDB Cluster on Linux

This section covers installation methods for NDB Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms. For manual installation and setup instructions specific to Windows systems, see Section 22.2.3, “Installing NDB Cluster on Windows”.

Each NDB Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (`mysqld`). Management nodes require the management server daemon (`ndb_mgmd`); data nodes require the data node daemon (`ndbd` or `ndbmtd`). It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (`ndb_mgm`) on the management server host.

Installation of NDB Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a .tar.gz archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the NDB Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See Section 22.2.4, “Initial Configuration of NDB Cluster”.

22.2.2.1 Installing an NDB Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the binary archive from the NDB Cluster downloads page. (For the most recent 64-bit NDB 8.0 release, this is `mysql-cluster-gpl-8.0.16-linux-glibc2.12-x86_64.tar.gz`.) We assume that you have placed this file in each machine's `/var/tmp` directory.

If you require a custom binary, see Section 2.9.3, “Installing MySQL Using a Development Source Tree”.

Note

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see Section 22.2.4, "Initial Configuration of NDB Cluster").

SQL nodes. On each of the machines designated to host SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

   ```
   shell> groupadd mysql
   shell> useradd -g mysql -s /bin/false mysql
   ```

   The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named `mysql` to the `mysql` directory.

   Note

   The actual file and directory names vary according to the NDB Cluster version number.

   ```
   shell> cd /var/tmp
   shell> tar -C /usr/local -xzvf mysql-cluster-gpl-8.0.16-linux-glibc2.12-x86_64.tar.gz
   shell> ln -s /usr/local/mysql-cluster-gpl-8.0.16-linux-glibc2.12-x86_64 /usr/local/mysql
   ```

3. Change location to the `mysql` directory and set up the system databases using `mysqld --initialize` as shown here:

   ```
   shell> cd mysql
   shell> mysqld --initialize
   ```

   This generates a random password for the MySQL `root` account. If you do *not* want the random password to be generated, you can substitute the `--initialize-insecure` option for `--initialize`. In either case, you should review Section 2.10.1, "Initializing the Data Directory", for additional information before performing this step. See also Section 4.4.2, "`mysql_secure_installation` — Improve MySQL Installation Security".

4. Set the necessary permissions for the MySQL server and data directories:

   ```
   shell> chown -R root .
   shell> chown -R mysql data
   shell> chgrp -R mysql .
   ```

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

   ```
   shell> cp support-files/mysql.server /etc/rc.d/init.d/
   shell> chmod +x /etc/rc.d/init.d/mysql.server
   shell> chkconfig --add mysql.server
   ```

   (The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

Data nodes. Installation of the data nodes does not require the `mysqld` binary. Only the NDB Cluster data node executable `ndbd` (single-threaded) or `ndbmtd` (multithreaded) is required. These binaries can also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install the data node binaries on the data node hosts:

1. Change location to the `/var/tmp` directory, and extract the `ndbd` and `ndbmtd` binaries from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-cluster-gpl-8.0.16-linux-glibc2.12-x86_64.tar.gz
shell> cd mysql-cluster-gpl-8.0.16-linux-glibc2.12-x86_64
shell> cp bin/ndbd /usr/local/bin/ndbd
shell> cp bin/ndbmtd /usr/local/bin/ndbmtd
```

   (You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb*
```

The preceding steps should be repeated on each data node host.

Although only one of the data node executables is required to run an NDB Cluster data node, we have shown you how to install both `ndbd` and `ndbmtd` in the preceding instructions. We recommend that you do this when installing or upgrading NDB Cluster, even if you plan to use only one of them, since this will save time and trouble in the event that you later decide to change from one to the other.

Note

The data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See Section 22.2.4, “Initial Configuration of NDB Cluster”.)

Management nodes. Installation of the management node does not require the `mysqld` binary. Only the NDB Cluster management server (`ndb_mgmd`) is required; you most likely want to install the management client (`ndb_mgm`) as well. Both of these binaries also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root`, perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
```

```
shell> tar -zxvf mysql-cluster-gpl-8.0.16-linux-glibc2.12-x86_64.tar.gz
shell> cd mysql-cluster-gpl-8.0.16-linux-glibc2.12-x86_64
shell> cp bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*
```

In Section 22.2.4, “Initial Configuration of NDB Cluster”, we create configuration files for all of the nodes in our example NDB Cluster.

22.2.2.2 Installing NDB Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of NDB Cluster 8.0 node using RPM packages supplied by Oracle. For information about RPMs for previous versions of NDB Cluster, see Installation using old-style RPMs (NDB 7.5.3 and earlier).

As an alternative to the method described in this section, Oracle provides MySQL Repositories for NDB Cluster that are compatible with many common Linux distributions. Two repostories, listed here, are available for RPM-based distributions:

- For distributions using `yum` or `dnf`, you can use the MySQL Yum Repository for NDB Cluster. See *Installing MySQL NDB Cluster Using the Yum Repository*, for instructions and additional information.
- For SLES, you can use the MySQL SLES Repository for NDB Cluster. See *Installing MySQL NDB Cluster Using the SLES Repository*, for instructions and additional information.

RPMs are available for both 32-bit and 64-bit Linux platforms. The filenames for these RPMs use the following pattern:

```
mysql-cluster-community-data-node-8.0.16-1.el7.x86_64.rpm

mysql-cluster-license-component-ver-rev.distro.arch.rpm

    license:= {commercial | community}

    component: {management-server | data-node | server | client | other—see text}

    ver: major.minor.release

    rev: major[.minor]

    distro: {el6 | el7 | sles12}

    arch: {i686 | x86_64}
```

`license` indicates whether the RPM is part of a Commercial or Community release of NDB Cluster. In the remainder of this section, we assume for the examples that you are installing a Community release.

Possible values for *`component`*, with descriptions, can be found in the following table:

Table 22.5 Components of the NDB Cluster RPM distribution

Component	Description
`auto-installer`	NDB Cluster Auto Installer program; see Section 22.2.1, “The NDB Cluster Auto-Installer”, for usage

Component	Description
client	MySQL and NDB client programs; includes mysql client, ndb_mgm client, and other client tools
common	Character set and error message information needed by the MySQL server
data-node	ndbd and ndbmtd data node binaries
devel	Headers and library files needed for MySQL client development
embedded	Embedded MySQL server
embedded-compat	Backwards-compatible embedded MySQL server
embedded-devel	Header and library files for developing applications for embedded MySQL
java	JAR files needed for support of ClusterJ applications
libs	MySQL client libraries
libs-compat	Backwards-compatible MySQL client libraries
management-server	The NDB Cluster management server (ndb_mgmd)
memcached	Files needed to support ndbmemcache
minimal-debuginfo	Debug information for package server-minimal; useful when developing applications that use this package or when debugging this package
ndbclient	NDB client library for running NDB API and MGM API applications (libndbclient)
ndbclient-devel	Header and other files needed for developing NDB API and MGM API applications
nodejs	Files needed to set up Node.JS support for NDB Cluster
server	The MySQL server (mysqld) with NDB storage engine support included, and associated MySQL server programs
server-minimal	Minimal installation of the MySQL server for NDB and related tools
test	mysqltest, other MySQL test programs, and support files

A single bundle (`.tar` file) of all NDB Cluster RPMs for a given platform and architecture is also available. The name of this file follows the pattern shown here:

```
mysql-cluster-license-ver-rev.distro.arch.rpm-bundle.tar
```

You can extract the individual RPM files from this file using `tar` or your preferred tool for extracting archives.

The components required to install the three major types of NDB Cluster nodes are given in the following list:

- *Management node*: `management-server`
- *Data node*: `data-node`
- *SQL node*: `server` and `common`

In addition, the `client` RPM should be installed to provide the `ndb_mgm` management client on at least one management node. You may also wish to install it on SQL nodes, to have `mysql` and other MySQL client programs available on these. We discuss installation of nodes by type later in this section.

`ver` represents the three-part `NDB` storage engine version number in 8.0.*`x`* format, shown as `8.0.16` in the examples. `rev` provides the RPM revision number in *`major`*.*`minor`* format. In the examples shown in this section, we use `1.1` for this value.

The *`distro`* (Linux distribution) is one of `rhel5` (Oracle Linux 5, Red Hat Enterprise Linux 4 and 5), `el6` (Oracle Linux 6, Red Hat Enterprise Linux 6), `el7` (Oracle Linux 7, Red Hat Enterprise Linux 7), or `sles12` (SUSE Enterprise Linux 12). For the examples in this section, we assume that the host runs Oracle Linux 7, Red Hat Enterprise Linux 7, or the equivalent (`el7`).

`arch` is `i686` for 32-bit RPMs and `x86_64` for 64-bit versions. In the examples shown here, we assume a 64-bit platform.

The NDB Cluster version number in the RPM file names (shown here as `8.0.16`) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same version number*. The architecture should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs (`x86_64`) cannot be used with 32-bit operating systems (use `i686` for the latter).

Data nodes. On a computer that is to host an NDB Cluster data node it is necessary to install only the `data-node` RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv mysql-cluster-community-data-node-8.0.16-1.el7.x86_64.rpm
```

This installs the `ndbd` and `ndbmtd` data node binaries in `/usr/sbin`. Either of these can be used to run a data node process on this host.

SQL nodes. Copy the `server` and `common` RPMs to each machine to be used for hosting an NDB Cluster SQL node (`server` requires `common`). Install the `server` RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv mysql-cluster-community-server-8.0.16-1.el7.x86_64.rpm
```

This installs the MySQL server binary (`mysqld`), with `NDB` storage engine support, in the `/usr/sbin` directory. It also installs all needed MySQL Server support files and useful MySQL server programs, including the `mysql.server` and `mysqld_safe` startup scripts (in `/usr/share/mysql` and `/usr/bin`, respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

Important

You must use the versions of these RPMs released for NDB Cluster ; those released for the standard MySQL server do not provide support for the `NDB` storage engine.

To administer the SQL node (MySQL server), you should also install the `client` RPM, as shown here:

```
shell> rpm -Uhv mysql-cluster-community-client-8.0.16-1.el7.x86_64.rpm
```

This installs the `mysql` client and other MySQL client programs, such as `mysqladmin` and `mysqldump`, to `/usr/bin`.

Management nodes. To install the NDB Cluster management server, it is necessary only to use the `management-server` RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the `management-server` RPM downloaded from the MySQL website):

```
shell> rpm -Uhv mysql-cluster-commercial-management-server-8.0.16-1.el7.x86_64.rpm
```

This RPM installs the management server binary `ndb_mgmd` in the `/usr/sbin` directory. While this is the only program actually required for running a management node, it is also a good idea to have the `ndb_mgm` NDB Cluster management client available as well. You can obtain this program, as well as other `NDB` client programs such as `ndb_desc` and `ndb_config`, by installing the `client` RPM as described previously.

See Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”, for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster; see Section 22.2.4, “Initial Configuration of NDB Cluster”, for the relevant information.

It is very important that all of the Cluster RPMs to be installed have the same version number. The *`architecture`* designation should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs cannot be used with 32-bit operating systems.

Data nodes. On a computer that is to host a cluster data node it is necessary to install only the `server` RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-8.0.16-1.sles11.i386.rpm
```

Although this installs all NDB Cluster binaries, only the program `ndbd` or `ndbmtd` (both in `/usr/sbin`) is actually needed to run an NDB Cluster data node.

SQL nodes. On each machine to be used for hosting a cluster SQL node, install the `server` RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-8.0.16-1.sles11.i386.rpm
```

This installs the MySQL server binary (`mysqld`) with `NDB` storage engine support in the `/usr/sbin` directory, as well as all needed MySQL Server support files. It also installs the `mysql.server` and `mysqld_safe` startup scripts (in `/usr/share/mysql` and `/usr/bin`, respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

To administer the SQL node (MySQL server), you should also install the `client` RPM, as shown here:

```
shell> rpm -Uhv MySQL-Cluster-client-gpl-8.0.16-1.sles11.i386.rpm
```

This installs the `mysql` client program.

Management nodes. To install the NDB Cluster management server, it is necessary only to use the `server` RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the `server` RPM downloaded from the MySQL website):

```
```

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-8.0.16-1.sles11.i386.rpm
```

Although this RPM installs many other files, only the management server binary `ndb_mgmd` (in the `/usr/sbin` directory) is actually required for running a management node. The `server` RPM also installs `ndb_mgm`, the `NDB` management client.

See Section 2.5.4, “Installing MySQL on Linux Using RPM Packages from Oracle”, for general information about installing MySQL using RPMs supplied by Oracle. See Section 22.2.4, “Initial Configuration of NDB Cluster”, for information about required post-installation configuration.

22.2.2.3 Installing NDB Cluster Using .deb Files

The section provides information about installing NDB Cluster on Debian and related Linux distributions such Ubuntu using the `.deb` files supplied by Oracle for this purpose.

Oracle also provides an NDB Cluster APT repository for Debian and other distributions. See *Installing MySQL NDB Cluster Using the APT Repository*, for instructions and additional information.

Oracle provides `.deb` installer files for NDB Cluster for 32-bit and 64-bit platforms. For a Debian-based system, only a single installer file is necessary. This file is named using the pattern shown here, according to the applicable NDB Cluster version, Debian version, and architecture:

```
mysql-cluster-gpl-ndbver-debiandebianver-arch.deb
```

Here, *`ndbver`* is the 3-part `NDB` engine version number, *`debianver`* is the major version of Debian (`8` or `9`), and *`arch`* is one of `i686` or `x86_64`. In the examples that follow, we assume you wish to install NDB 8.0.16 on a 64-bit Debian 9 system; in this case, the installer file is named `mysql-cluster-gpl-8.0.16-debian9-x86_64.deb-bundle.tar`.

Once you have downloaded the appropriate `.deb` file, you can untar it, and then install it from the command line using `dpkg`, like this:

```
shell> dpkg -i mysql-cluster-gpl-8.0.16-debian9-i686.deb
```

You can also remove it using `dpkg` as shown here:

```
shell> dpkg -r mysql
```

The installer file should also be compatible with most graphical package managers that work with `.deb` files, such as `GDebi` for the Gnome desktop.

The `.deb` file installs NDB Cluster under `/opt/mysql/server-version/`, where *`version`* is the 2-part release series version for the included MySQL server. For NDB 8.0, this is always `5.7`. The directory layout is the same as that for the generic Linux binary distribution (see Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”), with the exception that startup scripts and configuration files are found in `support-files` instead of `share`. All NDB Cluster executables, such as `ndb_mgm`, `ndbd`, and `ndb_mgmd`, are placed in the `bin` directory.

22.2.2.4 Building NDB Cluster from Source on Linux

This section provides information about compiling NDB Cluster on Linux and other Unix-like platforms. Building NDB Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see Section 2.9, “Installing MySQL from Source”. For information about compiling NDB Cluster on Windows platforms, see Section 22.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”.

Building MySQL NDB Cluster 8.0 requires using the MySQL Server 8.0 sources. These are available from the MySQL downloads page at https://dev.mysql.com/downloads/. The archived source file should have a name similar to `mysql-8.0.16.tar.gz`. You can also obtain MySQL development sources from launchpad.net.

Note

In previous versions, building of NDB Cluster from standard MySQL Server sources was not supported. In MySQL 8.0 and NDB Cluster 8.0, this is no longer the case—*both products are now built from the same sources*.

The `WITH_NDBCLUSTER` option for `CMake` causes the binaries for the management nodes, data nodes, and other NDB Cluster programs to be built; it also causes `mysqld` to be compiled with `NDB` storage engine support. This option (or one of its aliases `WITH_NDBCLUSTER_STORAGE_ENGINE` and `WITH_PLUGIN_NDBCLUSTER`) is required when building NDB Cluster.

Important

The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if `CMake` cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about `CMake` options specific to building NDB Cluster, see Options for Compiling NDB Cluster.

After you have run `make && make install` (or your system's equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location.

Management nodes. When building from source and running the default `make install`, the management server and management client binaries (`ndb_mgmd` and `ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

Data nodes. The only executable required on a data node host is the data node binary `ndbd` or `ndbmtd`. (`mysqld`, for example, does not have to be present on the host machine.) By default, when building from source, this file is placed in the directory `/usr/local/mysql/bin`. For installing on multiple data node hosts, only `ndbd` or `ndbmtd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) The data node binary need not be in any particular location on the host's file system, as long as the location is known.

When compiling NDB Cluster from source, no special options are required for building multithreaded data node binaries. Configuring the build with `NDB` storage engine support causes `ndbmtd` to be built automatically; `make install` places the `ndbmtd` binary in the installation `bin` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

SQL nodes. If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system `root` user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in Section 2.9, “Installing MySQL from Source” to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from Section 2.9, “Installing MySQL from Source” on each machine. If you configure the build with a nondefault `PREFIX` option, you must adjust the directory accordingly.

In Section 22.2.4, “Initial Configuration of NDB Cluster”, we create configuration files for all of the nodes in our example NDB Cluster.

22.2.3 Installing NDB Cluster on Windows

This section describes installation procedures for NDB Cluster on Windows hosts. NDB Cluster 8.0 binaries for Windows can be obtained from https://dev.mysql.com/downloads/cluster/. For

information about installing NDB Cluster on Windows from a binary release provided by Oracle, see Section 22.2.3.1, “Installing NDB Cluster on Windows from a Binary Release”.

It is also possible to compile and install NDB Cluster from source on Windows using Microsoft Visual Studio. For more information, see Section 22.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”.

22.2.3.1 Installing NDB Cluster on Windows from a Binary Release

This section describes a basic installation of NDB Cluster on Windows using a binary “no-install” NDB Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see Section 22.2, “NDB Cluster Installation”), as shown in the following table:

Table 22.6 Network addresses of nodes in example cluster

Node	IP Address
Management node (`mgmd`)	198.51.100.10
SQL node (`mysqld`)	198.51.100.20
Data node "A" (`ndbd`)	198.51.100.30
Data node "B" (`ndbd`)	198.51.100.40

As on other platforms, the NDB Cluster host computer running an SQL node must have installed on it a MySQL Server binary (`mysqld.exe`). You should also have the MySQL client (`mysql.exe`) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (`ndb_mgmd.exe`); each data node requires the data node daemon (`ndbd.exe` or `ndbmtd.exe`). For this example, we refer to `ndbd.exe` as the data node executable, but you can install `ndbmtd.exe`, the multithreaded version of this program, instead, in exactly the same way. You should also install the management client (`ndb_mgm.exe`) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of NDB Cluster node.

Note

As with other Windows programs, NDB Cluster executables are named with the `.exe` file extension. However, it is not necessary to include the `.exe` extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as `mysqld`, `mysql`, `ndb_mgmd`, and so on. You should understand that, whether we refer (for example) to `mysqld` or `mysqld.exe`, either name means the same thing (the MySQL Server program).

For setting up an NDB Cluster using Oracles's `no-install` binaries, the first step in the installation process is to download the latest NDB Cluster Windows ZIP binary archive from https://dev.mysql.com/downloads/cluster/. This archive has a filename of the `mysql-cluster-gpl-`*`ver`*`-win`*`arch`*`.zip`, where *`ver`* is the `NDB` storage engine version (such as `8.0.16`), and *`arch`* is the architecture (`32` for 32-bit binaries, and `64` for 64-bit binaries). For example, the NDB Cluster 8.0.16 archive for 64-bit Windows systems is named `mysql-cluster-gpl-8.0.16-win64.zip`.

You can run 32-bit NDB Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit NDB Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit NDB Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

SQL node. We assume that you have placed a copy of the archive in the directory `C:\Documents and Settings\`*`username`*`\My Documents\Downloads` on the computer having the IP address 198.51.100.20, where *`username`* is the name of the current user. (You can obtain this name using

`ECHO %USERNAME%` on the command line.) To install and run NDB Cluster executables as Windows services, this user should be a member of the `Administrators` group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter `C:\`, which causes the Extraction Wizard to extract the archive to the directory `C:\mysql-cluster-gpl-`*`ver`*`-win`*`arch`*. Rename this directory to `C:\mysql`.

It is possible to install the NDB Cluster binaries to directories other than `C:\mysql\bin`; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than `C:\mysql` or `C:\Program Files\MySQL\MySQL Server 8.0`, or if the SQL node's data directory is in a location other than `C:\mysql\data` or `C:\Program Files\MySQL\MySQL Server 8.0\data`, extra configuration options must be used on the command line or added to the `my.ini` or `my.cnf` file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see Section 2.3.5, “Installing MySQL on Microsoft Windows Using a `noinstall` ZIP Archive”.

For a MySQL Server with NDB Cluster support to run as part of an NDB Cluster, it must be started with the options `--ndbcluster` and `--ndb-connectstring`. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
# Options for mysqld process:
ndbcluster                      # run NDB storage engine
ndb-connectstring=198.51.100.10  # location of management server
```

You can add other options used by this MySQL Server if desired (see Section 2.3.5.2, “Creating an Option File”), but the file must contain the options shown, at a minimum. Save this file as `C:\mysql\my.ini`. This completes the installation and setup for the SQL node.

Data nodes. An NDB Cluster data node on a Windows host requires only a single executable, one of either `ndbd.exe` or `ndbmtd.exe`. For this example, we assume that you are using `ndbd.exe`, but the same instructions apply when using `ndbmtd.exe`. On each computer where you wish to run a data node (the computers having the IP addresses 198.51.100.30 and 198.51.100.40), create the directories `C:\mysql`, `C:\mysql\bin`, and `C:\mysql\cluster-data`; then, on the computer where you downloaded and extracted the `no-install` archive, locate `ndbd.exe` in the `C:\mysql\bin` directory. Copy this file to the `C:\mysql\bin` directory on each of the two data node hosts.

To function as part of an NDB Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the `--ndb-connectstring` or `-c` option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
# Options for data node process:
ndb-connectstring=198.51.100.10  # location of management server
```

Save this file as `C:\mysql\my.ini` on the data node host. Create another text file containing the same information and save it on as `C:mysql\my.ini` on the other data node host, or copy the my.ini file from the first data node host to the second one, making sure to place the copy in the second data node's `C:\mysql` directory. Both data node hosts are now ready to be used in the NDB Cluster, which leaves only the management node to be installed and configured.

Management node. The only executable program required on a computer used for hosting an NDB Cluster management node is the management server program `ndb_mgmd.exe`. However, in order to administer the NDB Cluster once it has been started, you should also install the NDB Cluster management client program `ndb_mgm.exe` on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the `no-install` archive;

this should be the directory `C:\mysql\bin` on the SQL node host. Create the directory `C:\mysql\bin` on the computer having the IP address 198.51.100.10, then copy both programs to this directory.

You should now create two configuration files for use by `ndb_mgmd.exe`:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the NDB Cluster global configuration file (see item 2).

   To create this file, start a new text file in Notepad or another text editor, and enter the following information:

   ```
   [mysql_cluster]
   # Options for management node process
   config-file=C:/mysql/bin/config.ini
   ```

   Save this file as the text file `C:\mysql\bin\my.ini`.

2. A global configuration file from which the management node can obtain configuration information governing the NDB Cluster as a whole. At a minimum, this file must contain a section for each node in the NDB Cluster, and the IP addresses or hostnames for the management node and all data nodes (`HostName` configuration parameter). It is also advisable to include the following additional information:

   - The IP address or hostname of any SQL nodes
   - The data memory and index memory allocated to each data node (`DataMemory` and `IndexMemory` configuration parameters)
   - The number of replicas, using the `NoOfReplicas` configuration parameter (see Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”)
   - The directory where each data node stores it data and log file, and the directory where the management node keeps its log files (in both cases, the `DataDir` configuration parameter)

   Create a new text file using a text editor such as Notepad, and input the following information:

   ```
   [ndbd default]
   # Options affecting ndbd processes on all data nodes:
   NoOfReplicas=2                      # Number of replicas
   DataDir=C:/mysql/cluster-data       # Directory for each data node's data files
                                       # Forward slashes used in directory path,
                                       # rather than backslashes. This is correct;
                                       # see Important note in text
   DataMemory=80M    # Memory allocated to data storage
   IndexMemory=18M   # Memory allocated to index storage
                     # For DataMemory and IndexMemory, we have used the
                     # default values. Since the "world" database takes up
                     # only about 500KB, this should be more than enough for
                     # this example Cluster setup.

   [ndb_mgmd]
   # Management process options:
   HostName=198.51.100.10              # Hostname or IP address of management node
   DataDir=C:/mysql/bin/cluster-logs   # Directory for management node log files

   [ndbd]
   # Options for data node "A":
                                 # (one [ndbd] section per data node)
   HostName=198.51.100.30        # Hostname or IP address

   [ndbd]
   # Options for data node "B":
   HostName=198.51.100.40        # Hostname or IP address
   ```

```
[mysqld]
# SQL node options:
HostName=198.51.100.20          # Hostname or IP address
```

Save this file as the text file `C:\mysql\bin\config.ini`.

Important

A single backslash character (`\`) cannot be used when specifying directory paths in program options or configuration files used by NDB Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (`\\`), or replace the backslash with a forward slash character (`/`). For example, the following line from the `[ndb_mgmd]` section of an NDB Cluster `config.ini` file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\\bin\\cluster-logs  # Escaped backslashes
```

```
DataDir=C:/mysql/bin/cluster-logs     # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in NDB Cluster program options and configuration files on Windows.

22.2.3.2 Compiling and Installing NDB Cluster from Source on Windows

Oracle provides precompiled NDB Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile NDB Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- To build NDB Cluster 8.0, use the MySQL Server 8.0 sources, which you can obtain from https://dev.mysql.com/downloads/.

  Formerly, NDB Cluster used its own source code. In MySQL 8.0 and NDB Cluster 8.0, this is no longer the case, and *both products are now built from the same source*.

- You must configure the build using the `WITH_NDBCLUSTER` option in addition to any other build options you wish to use with `CMake`. `WITH_NDBCLUSTER_STORAGE_ENGINE` and `WITH_PLUGIN_NDBCLUSTER` are supported as aliases for `WITH_NDBCLUSTER`, and work in exactly the same way.

Important

The `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if `CMake` cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. (Bug #12379735) Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about `CMake` options specific to building NDB Cluster, see Options for Compiling NDB Cluster.

Once the build process is complete, you can create a Zip archive containing the compiled binaries; Section 2.9.2, “Installing MySQL Using a Standard Source Distribution” provides the commands needed to perform this task on Windows systems. The NDB Cluster binaries can be found in the `bin`

directory of the resulting archive, which is equivalent to the `no-install` archive, and which can be installed and configured in the same manner. For more information, see Section 22.2.3.1, “Installing NDB Cluster on Windows from a Binary Release”.

22.2.3.3 Initial Startup of NDB Cluster on Windows

Once the NDB Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the NDB Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process. The output should appear similar to what is shown here:

```
C:\mysql\bin> ndb_mgmd
2010-06-23 07:53:34 [MgmtSrvr] INFO -- NDB Cluster Management Server. mysql-8.0.16-ndb-8.0.16
2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

   The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used NDB Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of NDB Cluster data node processes running on Windows.) For this reason, do not close the window in which `ndb_mgmd.exe` is running; doing so kills the management node process. (See Section 22.2.3.4, “Installing NDB Cluster Processes as Windows Services”, where we show how to install and run NDB Cluster processes as Windows services.)

   The required `-f` option tells the management node where to find the global configuration file (`config.ini`). The long form of this option is `--config-file`.

   Important

   An NDB Cluster management node caches the configuration data that it reads from `config.ini`; once it has created a configuration cache, it ignores the `config.ini` file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-read `config.ini` after you have corrected any errors in it. You can do this by starting `ndb_mgmd.exe` with the `--reload` or `--initial` option on the command line. Either of these options works to refresh the configuration cache.

   It is not necessary or advisable to use either of these options in the management node's `my.ini` file.

   For additional information about options which can be used with `ndb_mgmd`, see Section 22.4.4, “`ndb_mgmd` — The NDB Cluster Management Server Daemon”, as well as Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

2. On each of the data node hosts, run the command shown here to start the data node processes:

```
C:\mysql\bin> ndbd
2010-06-23 07:53:46 [ndbd] INFO -- Configuration fetched from 'localhost:1186', generation: 1
```

   In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is

running; doing so kills `ndbd.exe`. (For more information, see Section 22.2.3.4, “Installing NDB Cluster Processes as Windows Services”.)

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node host, start the NDB Cluster management client `ndb_mgm.exe`, which should be in `C:\mysql\bin` on the management node host. (Do not try to re-use the console window where `ndb_mgmd.exe` is running by typing **CTRL**+**C**, as this kills the management node.) The resulting output should look like this:

```
C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm>
```

When the prompt `ndb_mgm>` appears, this indicates that the management client is ready to receive NDB Cluster management commands. You can observe the status of the data nodes as they start by entering `ALL STATUS` at the management client prompt. This command causes a running report of the data nodes's startup sequence, which should look something like this:

```
ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186
Node 2: starting (Last completed phase 3) (mysql-8.0.16-ndb-8.0.16)
Node 3: starting (Last completed phase 3) (mysql-8.0.16-ndb-8.0.16)

Node 2: starting (Last completed phase 4) (mysql-8.0.16-ndb-8.0.16)
Node 3: starting (Last completed phase 4) (mysql-8.0.16-ndb-8.0.16)

Node 2: Started (version 8.0.16)
Node 3: Started (version 8.0.16)

ndb_mgm>
```

Note

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the `ndb_mgm` client. For more information, see Section 22.5.2, “Commands in the NDB Cluster Management Client”.

The output produced by `ALL STATUS` is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the NDB Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave `ndb_mgm.exe` running; it has no negative impact on the performance of the NDB Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the NDB Cluster binaries (if you are following our example, this is `C:\mysql\bin`).

Start the SQL node by invoking `mysqld.exe` from the command line, as shown here:

```
C:\mysql\bin> mysqld --console
```

The `--console` option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it out without the `--console` option, so that logging is performed normally.)

In the console window where the management client (`ndb_mgm.exe`) is running on the management node host, enter the `SHOW` command, which should produce output similar to what is shown here:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=2    @198.51.100.30  (Version: 8.0.16-ndb-8.0.16, Nodegroup: 0, *)
id=3    @198.51.100.40  (Version: 8.0.16-ndb-8.0.16, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1    @198.51.100.10  (Version: 8.0.16-ndb-8.0.16)

[mysqld(API)]   1 node(s)
id=4    @198.51.100.20  (Version: 8.0.16-ndb-8.0.16)
```

You can also verify that the SQL node is connected to the NDB Cluster in the `mysql` client (`mysql.exe`) using the `SHOW ENGINE NDB STATUS` statement.

You should now be ready to work with database objects and data using NDB Cluster 's `NDBCLUSTER` storage engine. See Section 22.2.6, “NDB Cluster Example with Tables and Data”, for more information and examples.

You can also install `ndb_mgmd.exe`, `ndbd.exe`, and `ndbmtd.exe` as Windows services. For information on how to do this, see Section 22.2.3.4, “Installing NDB Cluster Processes as Windows Services”).

22.2.3.4 Installing NDB Cluster Processes as Windows Services

Once you are satisfied that NDB Cluster is running as desired, you can install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `SC START` and `SC STOP` commands, or using the Windows graphical `Services` utility. `NET START` and `NET STOP` commands can also be used.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'NDB Cluster Management Server'
  as '"C:\mysql\bin\ndbd.exe" "--service=ndb_mgmd"'
Service successfully installed.
```

Important

When installing an NDB Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error `The system cannot find the file specified`.

The `--install` option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help`, you can specify the location using the `--config-file` option.

Now you should be able to start and stop the management server like this:

```
C:\> SC START ndb_mgmd

C:\> SC STOP ndb_mgmd
```

Note

If using `NET` commands, you can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```
C:\> NET START 'NDB Cluster Management Server'
The NDB Cluster Management Server service is starting.
The NDB Cluster Management Server service was started successfully.

C:\> NET STOP  'NDB Cluster Management Server'
The NDB Cluster Management Server service is stopping..
The NDB Cluster Management Server service was stopped successfully.
```

It is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than `ndb_mgmd`, append it to the `--install` option, as shown in this example:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmd1
Installing service 'NDB Cluster Management Server'
  as '"C:\mysql\bin\ndb_mgmd.exe" "--service=mgmd1"'
Service successfully installed.
```

Now you should be able to start or stop the service using the name you have specified, like this:

```
C:\> SC START mgmd1

C:\> SC STOP mgmd1
```

To remove the management node service, use `SC DELETE` *`service_name`*:

```
C:\> SC DELETE mgmd1
```

Alternatively, invoke `ndb_mgmd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove
Removing service 'NDB Cluster Management Server'
Service successfully removed.
```

If you installed the service using a service name other than the default, pass the service name as the value of the `ndb_mgmd.exe --remove` option, like this:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgmd1
Removing service 'mgmd1'
Service successfully removed.
```

Installation of an NDB Cluster data node process as a Windows service can be done in a similar fashion, using the `--install` option for `ndbd.exe` (or `ndbmtd.exe`), as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'NDB Cluster Data Node Daemon' as '"C:\mysql\bin\ndbd.exe" "--service=ndbd"'
Service successfully installed.
```

Now you can start or stop the data node as shown in the following example:

```
C:\> SC START ndbd

C:\> SC STOP ndbd
```

To remove the data node service, use `SC DELETE service_name`:

```
C:\> SC DELETE ndbd
```

Alternatively, invoke `ndbd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'NDB Cluster Data Node Daemon'
Service successfully removed.
```

As with `ndb_mgmd.exe` (and `mysqld.exe`), when installing `ndbd.exe` as a Windows service, you can also specify a name for the service as the value of `--install`, and then use it when starting or stopping the service, like this:

```
C:\> C:\mysql\bin\ndbd.exe --install=dnode1
Installing service 'dnode1' as '"C:\mysql\bin\ndbd.exe" "--service=dnode1"'
Service successfully installed.

C:\> SC START dnode1

C:\> SC STOP dnode1
```

If you specified a service name when installing the data node service, you can use this name when removing it as well, as shown here:

```
C:\> SC DELETE dnode1
```

Alternatively, you can pass the service name as the value of the `ndbd.exe --remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove=dnode1
Removing service 'dnode1'
Service successfully removed.
```

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using `mysqld --install`, `SC START`, `SC STOP`, and `SC DELETE` (or `mysqld --remove`). `NET` commands can also be used to start or stop a service. For additional information, see Section 2.3.5.8, “Starting MySQL as a Windows Service”.

22.2.4 Initial Configuration of NDB Cluster

In this section, we discuss manual configuration of an installed NDB Cluster by creating and editing configuration files.

NDB Cluster also provides a GUI installer which can be used to perform the configuration without the need to edit text files in a separate application. For more information, see Section 22.2.1, “The NDB Cluster Auto-Installer”.

For our four-node, four-host NDB Cluster (see Cluster nodes and host computers), it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a *connection string* that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

  For more information on connection strings, see Section 22.3.3.3, “NDB Cluster Connection Strings”.

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

Configuring the data nodes and SQL nodes. The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

Note

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
[mysqld]
# Options for mysqld process:
ndbcluster                      # run NDB storage engine

[mysql_cluster]
# Options for NDB Cluster processes:
ndb-connectstring=198.51.100.10  # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

Important

Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[mysqld]` and `[mysql_cluster]` sections of the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. This is by design.

Configuring the management node. The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2    # Number of replicas
DataMemory=80M    # How much memory to allocate for data storage

[ndb_mgmd]
# Management process options:
HostName=198.51.100.10          # Hostname or IP address of MGM node
DataDir=/var/lib/mysql-cluster  # Directory for MGM node log files

[ndbd]
# Options for data node "A":
                                # (one [ndbd] section per data node)
HostName=198.51.100.30          # Hostname or IP address
NodeId=2                        # Node ID for this data node
DataDir=/usr/local/mysql/data   # Directory for this data node's data files

[ndbd]
# Options for data node "B":
HostName=198.51.100.40          # Hostname or IP address
NodeId=3                        # Node ID for this data node
DataDir=/usr/local/mysql/data   # Directory for this data node's data files
```

```
[mysqld]
# SQL node options:
HostName=198.51.100.20          # Hostname or IP address
                                # (additional mysqld connections can be
                                # specified for this node for various
                                # purposes such as running ndb_restore)
```

Note

The `world` database can be downloaded from https://dev.mysql.com/doc/index-other.html.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in Section 22.2.5, “Initial Startup of NDB Cluster”.

For more detailed information about the available NDB Cluster configuration parameters and their uses, see Section 22.3.3, “NDB Cluster Configuration Files”, and Section 22.3, “Configuration of NDB Cluster”. For configuration of NDB Cluster as relates to making backups, see Section 22.5.3.3, “Configuration for NDB Cluster Backups”.

Note

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

22.2.5 Initial Startup of NDB Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

   ```
   shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
   ```

   The first time that it is started, `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. (See Section 22.4.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”, for details.)

   For additional options which can be used with `ndb_mgmd`, see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

2. On each of the data node hosts, run this command to start the `ndbd` process:

   ```
   shell> ndbd
   ```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
```

```
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=2    @198.51.100.30  (Version: 8.0.16-ndb-8.0.16, Nodegroup: 0, *)
id=3    @198.51.100.40  (Version: 8.0.16-ndb-8.0.16, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1    @198.51.100.10  (Version: 8.0.16-ndb-8.0.16)

[mysqld(API)]   1 node(s)
id=4    @198.51.100.20  (Version: 8.0.16-ndb-8.0.16)
```

The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as an NDB Cluster API node.

Note

The IP address shown for a given NDB Cluster SQL or other API node in the output of `SHOW` is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in NDB Cluster. See Section 22.2.6, “NDB Cluster Example with Tables and Data”, for a brief discussion.

22.2.6 NDB Cluster Example with Tables and Data

Note

The information in this section applies to NDB Cluster running on both Unix and Windows platforms.

Working with database tables and data in NDB Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

- For a table to be replicated in the cluster, it must use the `NDBCLUSTER` storage engine. To specify this, use the `ENGINE=NDBCLUSTER` or `ENGINE=NDB` option when creating the table:

  ```
  CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
  ```

  Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDBCLUSTER`:

  ```
  ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
  ```

- Every `NDBCLUSTER` table has a primary key. If no primary key is defined by the user when a table is created, the `NDBCLUSTER` storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` options. Suppose that you have the `world` sample database on another MySQL server that does not support NDB Cluster, and you want to export the `City` table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
```

```
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY  (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the `NDBCLUSTER` storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY  (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `198.51.100.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql`; for example, in the `/tmp` directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
```

```
Your MySQL connection id is 1 to server version: 8.0.16-ndb-8.0.16

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

We simply use the MySQL server's `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see Section 2.10.4, “Securing the Initial MySQL Account”.

It is worth taking into account that NDB Cluster nodes do *not* make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) effects only applications that access the SQL node, not interaction between nodes. See Section 22.5.12.2, “NDB Cluster and MySQL Privileges”, for more information.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----------+------------+
| Name      | Population |
+-----------+------------+
| Bombay    |   10500000 |
| Seoul     |    9981619 |
| São Paulo |    9968485 |
| Shanghai  |    9696300 |
| Jakarta   |    9604900 |
+-----------+------------+
5 rows in set (0.34 sec)

mysql> \q
Bye

shell>
```

Applications that use MySQL can employ standard APIs to access `NDB` tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the `SELECT` statement just shown by using the PHP 5.X `mysqli` extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
  "http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
  <meta http-equiv="Content-Type"
          content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
  # connect to SQL node:
  $link = new mysqli('198.51.100.20', 'root', 'root_password', 'world');
  # parameters for mysqli constructor are:
  #   host, user, password, database

  if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());
```

```
  $query = "SELECT Name, Population
            FROM City
            ORDER BY Population DESC
            LIMIT 5";

  # if no errors...
  if( $result = $link->query($query) )
  {
?>
<table border="1" width="40%" cellpadding="4" cellspacing ="1">
  <tbody>
  <tr>
    <th width="10%">City</th>
    <th>Population</th>
  </tr>
<?
    # then display the results...
    while($row = $result->fetch_object())
      printf("<tr>\n  <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
              $row->Name, $row->Population);
?>
  </tbody
</table>
<?
  # ...and verify the number of rows that were retrieved
    printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
  }
  else
    # otherwise, tell us what went wrong
    echo mysqli_error();

  # free the result set and the mysqli connection object
  $result->close();
  $link->close();
?>
</body>
</html>
```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

22.2.7 Safe Shutdown and Restart of NDB Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. (See Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”, for more information about this option.) The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmtd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `SC STOP service_name` or `NET STOP service_name`.

To restart the cluster on Unix platforms, run these commands:

- On the management host (`198.51.100.10` in our example setup):

  ```
  shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
  ```

- On each of the data node hosts (`198.51.100.30` and `198.51.100.40`):

```
shell> ndbd
```

- Use the ndb_mgm client to verify that both data nodes have started successfully.
- On the SQL host (198.51.100.20):

```
shell> mysqld_safe &
```

On Windows platforms, assuming that you have installed all NDB Cluster processes as Windows services using the default service names (see Section 22.2.3.4, “Installing NDB Cluster Processes as Windows Services”), you can restart the cluster as follows:

- On the management host (198.51.100.10 in our example setup), execute the following command:

```
C:\> SC START ndb_mgmd
```

- On each of the data node hosts (198.51.100.30 and 198.51.100.40), execute the following command:

```
C:\> SC START ndbd
```

- On the management node host, use the ndb_mgm client to verify that the management node and both data nodes have started successfully (see Section 22.2.3.3, “Initial Startup of NDB Cluster on Windows”).
- On the SQL node host (198.51.100.20), execute the following command:

```
C:\> SC START mysql
```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a *rolling restart* of the cluster. For more information about doing this, see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”.

22.2.8 Upgrading and Downgrading NDB Cluster

This section provides information about NDB Cluster software and table file compatibility between different NDB Cluster 8.0 releases with regard to performing upgrades and downgrades as well as compatibility matrices and notes. You are expected already to be familiar with installing and configuring an NDB Cluster prior to attempting an upgrade or downgrade. See Section 22.3, “Configuration of NDB Cluster”.

Important

Only compatibility between MySQL versions with regard to NDBCLUSTER is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the NDB Cluster software*. See Section 2.11, “Upgrading MySQL”.

Known Issues. The following issues are known to occur when upgrading to or between NDB 8.0 releases:

- Online downgrades from NDB 8.0.14 to previous releases are not supported. Tables created in NDB 8.0.14 are not backwards compatible with previous releases. This is due to a change in usage of

the extra metadata property implemented by NDB tables to provide full support for the MySQL data dictionary.

For more information, see NDB table extra metadata changes. See also Chapter 14, *MySQL Data Dictionary*.

22.3 Configuration of NDB Cluster

A MySQL server that is part of an NDB Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the NDB storage engine. This engine is also referred to sometimes as NDBCLUSTER, although NDB is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the NDB storage engine disabled. To enable NDB, you must modify the server's my.cnf configuration file, or start the server with the --ndbcluster option.

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on localhost. However, should you need to specify that its location is elsewhere, this can be done in my.cnf, or with the mysql client. Before the NDB storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about --ndbcluster and other mysqld options specific to NDB Cluster, see MySQL Server Options for NDB Cluster.

You can use also the NDB Cluster Auto-Installer to set up and deploy an NDB Cluster on one or more hosts using a browser-based GUI. For more information, see The NDB Cluster Auto-Installer (NDB 7.5).

For general information about installing NDB Cluster, see Section 22.2, “NDB Cluster Installation”.

22.3.1 Quick Test Setup of NDB Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional NDB Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as /var/lib/mysql-cluster, by executing the following command as the system root user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named config.ini that contains the following information. Substitute appropriate values for HostName and DataDir as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
# respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld  default]
[ndb_mgmd default]
[tcp default]
```

```
[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

For command-line options which can be used when starting `ndbd`, see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

By default, `ndbd` looks for the management server at `localhost` on port 1186.

Note

If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 8.0.17

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
*************************** 12. row ***************************
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
*************************** 13. row ***************************
```

```
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an `NDBCLUSTER` table:

```
shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
*************************** 1. row ***************************
       Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
---------------------
[ndbd(NDB)]     1 node(s)
id=2    @127.0.0.1  (Version: 8.0.16-ndb-8.0.16, Nodegroup: 0, *)

[ndb_mgmd(MGM)] 1 node(s)
id=1    @127.0.0.1  (Version: 8.0.16-ndb-8.0.16)

[mysqld(API)]   3 node(s)
id=3    @127.0.0.1  (Version: 8.0.16-ndb-8.0.16)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working NDB Cluster . You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

22.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables

The next several sections provide summary tables of NDB Cluster node configuration parameters used in the `config.ini` file to govern various aspects of node behavior, as well as of options and variables read by `mysqld` from a `my.cnf` file or from the command line when run as an NDB Cluster process. Each of the node parameter tables lists the parameters for a given type (`ndbd`, `ndb_mgmd`, `mysqld`, `computer`, `tcp`, `shm`, or `sci`). All tables include the data type for the parameter, option, or variable, as well as its default, mimimum, and maximum values as applicable.

Considerations when restarting nodes. For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked as `node` online—that is,

without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes`. In addition, it is the generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

Note

`4294967039` often appears as a maximum value in these tables. This value is defined in the `NDBCLUSTER` sources as `MAX_INT_RNIL` and is equal to `0xFFFFFEFF`, or $2^{32} - 2^8 - 1$.

22.3.2.1 NDB Cluster Data Node Configuration Parameters

The listings in this section provide information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring NDB Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see Section 22.3.3.6, “Defining NDB Cluster Data Nodes”.

These parameters also apply to `ndbmtd`, the multithreaded version of `ndbd`. For more information, see Section 22.4.3, “`ndbmtd` — The NDB Cluster Data Node Daemon (Multi-Threaded)”.

- `Arbitration`: How arbitration should be performed to avoid split-brain issues in the event of node failure.
- `ArbitrationTimeout`: Maximum time (milliseconds) database partition waits for arbitration signal
- `BackupDataBufferSize`: Default size of databuffer for a backup (in bytes)
- `BackupDataDir`: Path to where to store backups. Note that the string '/BACKUP' is always appended to this setting, so that the *effective* default is FileSystemPath/BACKUP.
- `BackupDiskWriteSpeedPct`: Sets the percentage of the data node's allocated maximum write speed (MaxDiskWriteSpeed) to reserve for LCPs when starting abackup.
- `BackupLogBufferSize`: Default size of log buffer for a backup (in bytes)
- `BackupMaxWriteSize`: Maximum size of file system writes made by backup (in bytes)

- `BackupMemory`: Total memory allocated for backups per node (in bytes)
- `BackupReportFrequency`: Frequency of backup status reports during backup in seconds
- `BackupWriteSize`: Default size of file system writes made by backup (in bytes)
- `BatchSizePerLocalScan`: Used to calculate the number of lock records for scan with hold lock
- `BuildIndexThreads`: Number of threads to use for building ordered indexes during a system or node restart. Also applies when running ndb_restore --rebuild-indexes. Setting this parameter to 0 disables multithreaded building of ordered indexes.
- `CompressedBackup`: Use zlib to compress backups as they are written
- `CompressedLCP`: Write compressed LCPs using zlib
- `ConnectCheckIntervalDelay`: Time between data node connectivity check stages. Data node is considered suspect after 1 interval and dead after 2 intervals with no response.
- `CrashOnCorruptedTuple`: When enabled, forces node to shut down whenever it detects a corrupted tuple.
- `DataDir`: Data directory for this node
- `DataMemory`: Number of bytes on each data node allocated for storing data; subject to available system RAM and size of IndexMemory.
- `DefaultHashMapSize`: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840. Intended primarily for upgrades and downgrades within NDB 7.2.
- `DictTrace`: Enable DBDICT debugging; for NDB development
- `DiskIOThreadPool`: Number of unbound threads for file access (currently only for Disk Data); known as IOThreadPool before MySQL Cluster NDB 6.4.3.
- `Diskless`: Run without using the disk
- `DiskPageBufferEntries`: Number of 32K page entries to allocate in DiskPageBufferMemory. Very large disk transactions may require increasing this value.
- `DiskPageBufferMemory`: Number of bytes on each data node allocated for the disk page buffer cache
- `DiskSyncSize`: Amount of data written to file before a synch is forced
- `EnablePartialLcp`: Enable partial LCP (true); if this disabled (false), all LCPs write full checkpoints.
- `EnableRedoControl`: Enable adaptive checkpointing speed for controlling redo log usage
- `EventLogBufferSize`: Size of circular buffer for NDB log events within data nodes.
- `ExecuteOnComputer`: String referencing an earlier defined COMPUTER
- `ExtraSendBufferMemory`: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.
- `FileSystemPath`: Path to directory where the data node stores its data (directory must exist)
- `FileSystemPathDataFiles`: Path to directory where the data node stores its Disk Data files. The default value is FilesystemPathDD, if set; otherwise, FilesystemPath is used if it is set; otherwise, the value of DataDir is used.
- `FileSystemPathDD`: Path to directory where the data node stores its Disk Data and undo files. The default value is FileSystemPath, if set; otherwise, the value of DataDir is used.

- `FileSystemPathUndoFiles`: Path to directory where the data node stores its undo files for Disk Data. The default value is FilesystemPathDD, if set; otherwise, FilesystemPath is used if it is set; otherwise, the value of DataDir is used.
- `FragmentLogFileSize`: Size of each redo log file
- `HeartbeatIntervalDbApi`: Time between API node-data node heartbeats. (API connection closed after 3 missed heartbeats)
- `HeartbeatIntervalDbDb`: Time between data node-to-data node heartbeats; data node considered dead after 3 missed heartbeats
- `HeartbeatOrder`: Sets the order in which data nodes check each others' heartbeats for determining whether a given node is still active and connected to the cluster. Must be zero for all data nodes or distinct nonzero values for all data nodes; see documentation for further guidance.
- `HostName`: Host name or IP address for this data node.
- `IndexMemory`: Number of bytes on each data node allocated for storing indexes; subject to available system RAM and size of DataMemory.
- `IndexStatAutoCreate`: Enable/disable automatic statistics collection when indexes are created.
- `IndexStatAutoUpdate`: Monitor indexes for changes and trigger automatic statistics updates
- `IndexStatSaveScale`: Scaling factor used in determining size of stored index statistics.
- `IndexStatSaveSize`: Maximum size in bytes for saved statistics per index.
- `IndexStatTriggerPct`: Threshold percent change in DML operations for index statistics updates. The value is scaled down by IndexStatTriggerScale.
- `IndexStatTriggerScale`: Scale down IndexStatTriggerPct by this amount, multiplied by the base 2 logarithm of the index size, for a large index. Set to 0 to disable scaling.
- `IndexStatUpdateDelay`: Minimum delay between automatic index statistics updates for a given index. 0 means no delay.
- `InitFragmentLogFiles`: Initialize fragment logfiles (sparse/full)
- `InitialLogFileGroup`: Describes a log file group that is created during an initial start. See documentation for format.
- `InitialNoOfOpenFiles`: Initial number of files open per data node. (One thread is created per file)
- `InitialTablespace`: Describes a tablespace that is created during an initial start. See documentation for format.
- `InsertRecoveryWork`: Percentage of RecoveryWork used for inserted rows; has no effect unless partial local checkpoints are in use
- `LateAlloc`: Allocate memory after the connection to the management server has been established.
- `LcpScanProgressTimeout`: Maximum time that local checkpoint fragment scan can be stalled before node is shut down to ensure systemwide LCP progress. Use 0 to disable.
- `LockExecuteThreadToCPU`: A comma-delimited list of CPU IDs
- `LockMaintThreadsToCPU`: CPU ID indicating which CPU runs the maintenance threads
- `LockPagesInMainMemory`: Previously: If set to true/1, then NDB Cluster data is not swapped out to disk. In MySQL 5.0.36/5.1.15 and later: 0=disable locking, 1=lock after memory allocation, 2=lock before memory allocation
- `LogLevelCheckpoint`: Log level of local and global checkpoint information printed to stdout

- `LogLevelCongestion`: Level of congestion information printed to stdout
- `LogLevelConnection`: Level of node connect/disconnect information printed to stdout
- `LogLevelError`: Transporter, heartbeat errors printed to stdout
- `LogLevelInfo`: Heartbeat and log information printed to stdout
- `LogLevelNodeRestart`: Level of node restart and node failure information printed to stdout
- `LogLevelShutdown`: Level of node shutdown information printed to stdout
- `LogLevelStartup`: Level of node startup information printed to stdout
- `LogLevelStatistic`: Level of transaction, operation, and transporter information printed to stdout
- `LongMessageBuffer`: Number of bytes allocated on each data node for internal long messages
- `MaxAllocate`: Maximum size of allocation to use when allocating memory for tables
- `MaxBufferedEpochs`: Allowed numbered of epochs that a subscribing node can lag behind (unprocessed epochs). Exceeding will cause lagging subscribers to be disconnected.
- `MaxBufferedEpochBytes`: Total number of bytes allocated for buffering epochs.
- `MaxDiskWriteSpeed`: Maximum number of bytes per second that can be written by LCP and backup when no restarts are ongoing.
- `MaxDiskWriteSpeedOtherNodeRestart`: Maximum number of bytes per second that can be written by LCP and backup when another node is restarting.
- `MaxDiskWriteSpeedOwnRestart`: Maximum number of bytes per second that can be written by LCP and backup when this node is restarting.
- `MaxFKBuildBatchSize`: Maximum scan batch size to use for building foreign keys. Increasing this value may speed up builds of foreign keys but impacts ongoing traffic as well.
- `MaxDMLOperationsPerTransaction`: Limit size of a transaction; aborts the transaction if it requires more than this many DML operations. Set to 0 to disable.
- `MaxLCPStartDelay`: Time in seconds that LCP polls for checkpoint mutex (to allow other data nodes to complete metadata synchronization), before putting itself in lock queue for parallel recovery of table data.
- `MaxNoOfAttributes`: Suggests a total number of attributes stored in database (sum over all tables)
- `MaxNoOfConcurrentIndexOperations`: Total number of index operations that can execute simultaneously on one data node
- `MaxNoOfConcurrentOperations`: Maximum number of operation records in transaction coordinator
- `MaxNoOfConcurrentScans`: Maximum number of scans executing concurrently on the data node
- `MaxNoOfConcurrentSubOperations`: Maximum number of concurrent subscriber operations
- `MaxNoOfConcurrentTransactions`: Maximum number of transactions executing concurrently on this data node, the total number of transactions that can be executed concurrently is this value times the number of data nodes in the cluster.
- `MaxNoOfFiredTriggers`: Total number of triggers that can fire simultaneously on one data node
- `MaxNoOfLocalOperations`: Maximum number of operation records defined on this data node
- `MaxNoOfLocalScans`: Maximum number of fragment scans in parallel on this data node

- `MaxNoOfOpenFiles`: Maximum number of files open per data node.(One thread is created per file)
- `MaxNoOfOrderedIndexes`: Total number of ordered indexes that can be defined in the system
- `MaxNoOfSavedMessages`: Maximum number of error messages to write in error log and maximum number of trace files to retain
- `MaxNoOfSubscribers`: Maximum number of subscribers (default 0 = MaxNoOfTables * 2)
- `MaxNoOfSubscriptions`: Maximum number of subscriptions (default 0 = MaxNoOfTables)
- `MaxNoOfTables`: Suggests a total number of NDB tables stored in the database
- `MaxNoOfTriggers`: Total number of triggers that can be defined in the system
- `MaxNoOfUniqueHashIndexes`: Total number of unique hash indexes that can be defined in the system
- `MaxParallelCopyInstances`: Number of parallel copies during node restarts. Default is 0, which uses number of LDMs on both nodes, to a maximum of 16.
- `MaxParallelScansPerFragment`: Maximum number of parallel scans per fragment. Once this limit is reached, scans are serialized.
- `MaxReorgBuildBatchSize`: Maximum scan batch size to use for reorganization of table partitions. Increasing this value may speed up table partition reorganization but impacts ongoing traffic as well.
- `MaxStartFailRetries`: Maximum retries when data node fails on startup, requires StopOnError = 0. Setting to 0 causes start attempts to continue indefinitely.
- `MaxUIBuildBatchSize`: Maximum scan batch size to use for building unique keys. Increasing this value may speed up builds of unique keys but impacts ongoing traffic as well.
- `MemReportFrequency`: Frequency of memory reports in seconds; 0 = report only when exceeding percentage limits
- `MinDiskWriteSpeed`: Minimum number of bytes per second that can be written by LCP and backup.
- `MinFreePct`: The percentage of memory resources to keep in reserve for restarts.
- `NodeGroup`: Node group to which the data node belongs; used only during initial start of cluster.
- `NodeId`: Number uniquely identifying the data node among all nodes in the cluster.
- `NoOfDiskPagesToDiskDuringRestartACC`: Disk checkpoint speed
- `NoOfFragmentLogFiles`: Number of 16 MB redo log files in each of 4 file sets belonging to the data node
- `NoOfReplicas`: Number of copies of all data in database; recommended value is 2 (default). Values greater than 2 are not supported in production.
- `Numa`: (Linux only; requires libnuma) Controls NUMA support. Setting to 0 permits system to determine use of interleaving by data node process; 1 means that it is determined by data node.
- `ODirect`: Use O_DIRECT file reads and writes when possible.
- `ODirectSyncFlag`: O_DIRECT writes are treated as synchronized writes; ignored when ODirect is not enabled, InitFragmentLogFiles is set to SPARSE, or both.
- `RealtimeScheduler`: When true, data node threads are scheduled as real-time threads. Default is false.
- `RecoveryWork`: Percentage of storage overhead for LCP files: greater value means less work in normal operations, more work during recovery

- `RedoBuffer`: Number bytes on each data node allocated for writing redo logs
- `RedoOverCommitCounter`: When RedoOverCommitLimit has been exceeded this many times, transactions are aborted, and operations are handled as specified by DefaultOperationRedoProblemAction.
- `RedoOverCommitLimit`: Each time that flushing the current redo buffer takes longer than this many seconds, the number of times that this has happened is compared to RedoOverCommitCounter.
- `RestartOnErrorInsert`: Control the type of restart caused by inserting an error (when StopOnError is enabled)
- `SchedulerExecutionTimer`: Number of microseconds to execute in scheduler before sending
- `SchedulerResponsiveness`: Set NDB scheduler response optimization 0-10; higher values provide better response time but lower throughput
- `SchedulerSpinTimer`: Number of microseconds to execute in scheduler before sleeping
- `ServerPort`: Port used to set up transporter for incoming connections from API nodes
- `SharedGlobalMemory`: Total number of bytes on each data node allocated for any use
- `StartFailRetryDelay`: Delay in seconds after start failure prior to retry; requires StopOnError = 0.
- `StartFailureTimeout`: Milliseconds to wait before terminating. (0=Wait forever)
- `StartNoNodeGroupTimeout`: Time to wait for nodes without a nodegroup before trying to start (0=forever)
- `StartPartialTimeout`: Milliseconds to wait before trying to start without all nodes. (0=Wait forever)
- `StartPartitionedTimeout`: Milliseconds to wait before trying to start partitioned. (0=Wait forever)
- `StartupStatusReportFrequency`: Frequency of status reports during startup
- `StopOnError`: When set to 0, the data node automatically restarts and recovers following node failures
- `StringMemory`: Default size of string memory (0 to 100 = % of maximum, 101+ = actual bytes)
- `TcpBind_INADDR_ANY`: Bind IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections)
- `TimeBetweenEpochs`: Time between epochs (synchronization used for replication)
- `TimeBetweenEpochsTimeout`: Timeout for time between epochs. Exceeding will cause node shutdown.
- `TimeBetweenGlobalCheckpoints`: Time between doing group commit of transactions to disk
- `TimeBetweenGlobalCheckpointsTimeout`: Minimum timeout for group commit of transactions to disk
- `TimeBetweenInactiveTransactionAbortCheck`: Time between checks for inactive transactions
- `TimeBetweenLocalCheckpoints`: Time between taking snapshots of the database (expressed in base-2 logarithm of bytes)
- `TimeBetweenWatchDogCheck`: Time between execution checks inside a data node

- `TimeBetweenWatchDogCheckInitial`: Time between execution checks inside a data node (early start phases when memory is allocated)
- `TotalSendBufferMemory`: Total memory to use for all transporter send buffers.
- `TransactionBufferMemory`: Dynamic buffer space (in bytes) for key and attribute data allocated for each data node
- `TransactionDeadlockDetectionTimeout`: Time transaction can spend executing within a data node. This is the time that the transaction coordinator waits for each data node participating in the transaction to execute a request. If the data node takes more than this amount of time, the transaction is aborted.
- `TransactionInactiveTimeout`: Milliseconds that the application waits before executing another part of the transaction. This is the time the transaction coordinator waits for the application to execute or send another part (query, statement) of the transaction. If the application takes too much time, then the transaction is aborted. Timeout = 0 means that the application never times out.
- `TwoPassInitialNodeRestartCopy`: Copy data in 2 passes during initial node restart, which enables multithreaded building of ordered indexes for such restarts.
- `UndoDataBuffer`: Number of bytes on each data node allocated for writing data undo logs
- `UndoIndexBuffer`: Number of bytes on each data node allocated for writing index undo logs
- `UseShm`: Use shared memory connections between nodes

The following parameters are specific to `ndbmtd`:

- `MaxNoOfExecutionThreads`: For ndbmtd only, specify maximum number of execution threads
- `NoOfFragmentLogParts`: Number of redo log file groups belonging to this data node; value must be an even multiple of 4.
- `ThreadConfig`: Used for configuration of multithreaded data nodes (ndbmtd). Default is an empty string; see documentation for syntax and other information.

22.3.2.2 NDB Cluster Management Node Configuration Parameters

The listing in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` section of a `config.ini` file for configuring NDB Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see Section 22.3.3.5, “Defining an NDB Cluster Management Server”.

- `ArbitrationDelay`: When asked to arbitrate, arbitrator waits this long before voting (milliseconds)
- `ArbitrationRank`: If 0, then management node is not arbitrator. Kernel selects arbitrators in order 1, 2
- `DataDir`: Data directory for this node
- `ExecuteOnComputer`: String referencing an earlier defined COMPUTER
- `ExtraSendBufferMemory`: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.
- `HeartbeatIntervalMgmdMgmd`: Time between management node-to-management node heartbeats; the connection between management node is considered lost after 3 missed heartbeats.
- `HeartbeatThreadPriority`: Set heartbeat thread policy and priority for management nodes; see manual for allowed values
- `HostName`: Host name or IP address for this management node.
- `Id`: Number identifying the management node (Id). Now deprecated; use NodeId instead.

- `LogDestination`: Where to send log messages: console, system log, or specified log file
- `NodeId`: Number uniquely identifying the management node among all nodes in the cluster.
- `PortNumber`: Port number to send commands to and fetch configuration from management server
- `PortNumberStats`: Port number used to get statistical information from a management server
- `TotalSendBufferMemory`: Total memory to use for all transporter send buffers
- `wan`: Use WAN TCP setting as default

Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See Section 22.3.3.5, “Defining an NDB Cluster Management Server”, for more information.

To add new management servers to a running NDB Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see Section 22.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

22.3.2.3 NDB Cluster SQL Node and API Node Configuration Parameters

The listing in this section provides information about parameters used in the `[mysqld]` and `[api]` sections of a `config.ini` file for configuring NDB Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- `ApiVerbose`: Enable NDB API debugging; for NDB development
- `ArbitrationDelay`: When asked to arbitrate, arbitrator waits this many milliseconds before voting
- `ArbitrationRank`: If 0, then API node is not arbitrator. Kernel selects arbitrators in order 1, 2
- `AutoReconnect`: Specifies whether an API node should reconnect fully when disconnected from the cluster
- `BatchByteSize`: The default batch size in bytes
- `BatchSize`: The default batch size in number of records
- `ConnectBackoffMaxTime`: Specifies longest time in milliseconds (~100ms resolution) to allow between connection attempts to any given data node by this API node. Excludes time elapsed while connection attempts are ongoing, which in worst case can take several seconds. Disable by setting to 0. If no data nodes are currently connected to this API node, StartConnectBackoffMaxTime is used instead.
- `ConnectionMap`: Specifies which data nodes to connect
- `DefaultHashMapSize`: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840. Intended primarily for upgrades and downgrades within NDB 7.2.
- `DefaultOperationRedoProblemAction`: How operations are handled in the event that RedoOverCommitCounter is exceeded
- `ExecuteOnComputer`: String referencing an earlier defined COMPUTER
- `ExtraSendBufferMemory`: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.

- `HeartbeatThreadPriority`: Set heartbeat thread policy and priority for API nodes; see manual for allowed values
- `HostName`: Host name or IP address for this SQL or API node.
- `Id`: Number identifying MySQL server or API node (Id). Now deprecated; use NodeId instead.
- `MaxScanBatchSize`: The maximum collective batch size for one scan
- `NodeId`: Number uniquely identifying the SQL node or API node among all nodes in the cluster.
- `StartConnectBackoffMaxTime`: Same as ConnectBackoffMaxTime except that this parameter is used in its place if no data nodes are connected to this API node.
- `TotalSendBufferMemory`: Total memory to use for all transporter send buffers
- `wan`: Use WAN TCP setting as default

For a discussion of MySQL server options for NDB Cluster, see MySQL Server Options for NDB Cluster; for information about MySQL server system variables relating to NDB Cluster, see NDB Cluster System Variables.

Note

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

22.3.2.4 Other NDB Cluster Configuration Parameters

The listings in this section provide information about parameters used in the `[computer]`, `[tcp]`, `[shm]`, and `[sci]` sections of a `config.ini` file for configuring NDB Cluster. For detailed descriptions and additional information about individual parameters, see Section 22.3.3.10, “NDB Cluster TCP/IP Connections”, Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”, or Section 22.3.3.13, “SCI Transport Connections in NDB Cluster”, as appropriate.

The following parameters apply to the `config.ini` file's `[computer]` section:

- `HostName`: Host name or IP address of this computer.
- `Id`: A unique identifier for this computer.

The following parameters apply to the `config.ini` file's `[tcp]` section:

- `Checksum`: If checksum is enabled, all signals between nodes are checked for errors
- `Group`: Used for group proximity; smaller value is interpreted as being closer
- `NodeId1`: ID of node (data node, API node, or management node) on one side of the connection
- `NodeId2`: ID of node (data node, API node, or management node) on one side of the connection
- `NodeIdServer`: Set server side of TCP connection
- `OverloadLimit`: When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.
- `PreSendChecksum`: If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors

- `Proxy`:
- `ReceiveBufferMemory`: Bytes of buffer for signals received by this node
- `SendBufferMemory`: Bytes of TCP buffer for signals sent from this node
- `SendSignalId`: Sends ID in each signal. Used in trace files. Defaults to true in debug builds.
- `TCP_MAXSEG_SIZE`: Value used for TCP_MAXSEG
- `TCP_RCV_BUF_SIZE`: Value used for SO_RCVBUF
- `TCP_SND_BUF_SIZE`: Value used for SO_SNDBUF
- `TcpBind_INADDR_ANY`: Bind InAddrAny instead of host name for server part of connection

The following parameters apply to the `config.ini` file's `[shm]` section:

- `Checksum`: If checksum is enabled, all signals between nodes are checked for errors
- `Group`:
- `NodeId1`: ID of node (data node, API node, or management node) on one side of the connection
- `NodeId2`: ID of node (data node, API node, or management node) on one side of the connection
- `NodeIdServer`: Set server side of SHM connection
- `OverloadLimit`: When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.
- `PreSendChecksum`: If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors
- `SendBufferMemory`: Bytes in shared memory buffer for signals sent from this node
- `SendSignalId`: Sends ID in each signal. Used in trace files.
- `ShmKey`: A shared memory key; when set to 1, this is calculated by NDB
- `ShmSpinTime`: When receiving, number of microseconds to spin before sleeping
- `ShmSize`: Size of shared memory segment
- `Signum`: Signal number to be used for signalling

The following parameters apply to the `config.ini` file's `[sci]` section:

- `Checksum`: If checksum is enabled, all signals between nodes are checked for errors
- `Group`:
- `Host1SciId0`: SCI-node ID for adapter 0 on Host1 (a computer can have two adapters)
- `Host1SciId1`: SCI-node ID for adapter 1 on Host1 (a computer can have two adapters)
- `Host2SciId0`: SCI-node ID for adapter 0 on Host2 (a computer can have two adapters)
- `Host2SciId1`: SCI-node ID for adapter 1 on Host2 (a computer can have two adapters)
- `NodeId1`: ID of node (data node, API node, or management node) on one side of the connection
- `NodeId2`: ID of node (data node, API node, or management node) on one side of the connection
- `NodeIdServer`:
- `OverloadLimit`: When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

- `SendLimit`: Transporter send buffer contents are sent when this number of bytes is buffered
- `SendSignalId`: Sends ID in each signal. Used in trace files.
- `SharedBufferSize`: Size of shared memory segment

22.3.2.5 NDB Cluster mysqld Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in an NDB Cluster. For a table showing *all* command-line options, server and status variables available for use with `mysqld`, see Section 5.1.4, "Server Option, System Variable, and Status Variable Reference".

- `Com_show_ndb_status`: Count of SHOW NDB STATUS statements
- `Handler_discover`: Number of times that tables have been discovered
- `ndb-batch-size`: Size (in bytes) to use for NDB transaction batches
- `ndb-blob-read-batch-bytes`: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.
- `ndb-blob-write-batch-bytes`: Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.
- `ndb-cluster-connection-pool`: Number of connections to the cluster used by MySQL
- `ndb-cluster-connection-pool-nodeids`: Comma-separated list of node IDs for connections to the cluster used by MySQL; the number of nodes in the list must be the same as the value set for --ndb-cluster-connection-pool
- `ndb-connectstring`: Point to the management server that distributes the cluster configuration
- `ndb-default-column-format`: Use this value (FIXED or DYNAMIC) by default for COLUMN_FORMAT and ROW_FORMAT options when creating or adding columns to a table.
- `ndb-deferred-constraints`: Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.
- `ndb-distribution`: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)
- `ndb-log-apply-status`: Cause a MySQL server acting as a slave to log mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID. Effective only if the server is started with the --ndbcluster option.
- `ndb-log-empty-epochs`: When enabled, causes epochs in which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.
- `ndb-log-empty-update`: When enabled, causes updates that produced no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.
- `ndb-log-exclusive-reads`: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts
- `ndb-log-orig`: Log originating server id and epoch in mysql.ndb_binlog_index table
- `ndb-log-transaction-id`: Write NDB transaction IDs in the binary log. Requires --log-bin-v1-events=OFF.
- `ndb-mgmd-host`: Set the host (and port, if desired) for connecting to management server
- `ndb-nodeid`: NDB Cluster node ID for this MySQL server

- `ndb-recv-thread-activation-threshold`: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads)
- `ndb-recv-thread-cpu-mask`: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.
- `ndb-transid-mysql-connection-map`: Enable or disable the ndb_transid_mysql_connection_map plugin; that is, enable or disable the INFORMATION_SCHEMA table having that name
- `ndb-wait-connected`: Time (in seconds) for the MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections
- `ndb-wait-setup`: Time (in seconds) for the MySQL server to wait for NDB engine setup to complete
- `ndb-allow-copying-alter-table`: Set to OFF to keep ALTER TABLE from using copying operations on NDB tables
- `Ndb_api_bytes_received_count`: Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node)
- `Ndb_api_bytes_received_count_session`: Amount of data (in bytes) received from the data nodes in this client session
- `Ndb_api_bytes_received_count_slave`: Amount of data (in bytes) received from the data nodes by this slave
- `Ndb_api_bytes_sent_count`: Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node)
- `Ndb_api_bytes_sent_count_slave`: Amount of data (in bytes) sent to the data nodes by this slave
- `Ndb_api_event_bytes_count_injector`: Number of bytes of events received by the NDB binary log injector thread
- `Ndb_api_event_data_count_injector`: Number of row change events received by the NDB binary log injector thread
- `Ndb_api_event_nondata_count_injector`: Number of events received, other than row change events, by the NDB binary log injector thread
- `Ndb_api_pk_op_count`: Number of operations based on or using primary keys by this MySQL Server (SQL node)
- `Ndb_api_pk_op_count_session`: Number of operations based on or using primary keys in this client session
- `Ndb_api_pk_op_count_slave`: Number of operations based on or using primary keys by this slave
- `Ndb_api_pruned_scan_count`: Number of scans that have been pruned to a single partition by this MySQL Server (SQL node)
- `Ndb_api_pruned_scan_count_session`: Number of scans that have been pruned to a single partition in this client session
- `Ndb_api_range_scan_count_slave`: Number of range scans that have been started by this slave
- `Ndb_api_read_row_count`: Total number of rows that have been read by this MySQL Server (SQL node)

- Ndb_api_read_row_count_session: Total number of rows that have been read in this client session
- Ndb_api_scan_batch_count_slave: Number of batches of rows received by this slave
- Ndb_api_table_scan_count: Number of table scans that have been started, including scans of internal tables, by this MySQL Server (SQL node)
- Ndb_api_table_scan_count_session: Number of table scans that have been started, including scans of internal tables, in this client session
- Ndb_api_trans_abort_count: Number of transactions aborted by this MySQL Server (SQL node)
- Ndb_api_trans_abort_count_session: Number of transactions aborted in this client session
- Ndb_api_trans_abort_count_slave: Number of transactions aborted by this slave
- Ndb_api_trans_close_count: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this MySQL Server (SQL node)
- Ndb_api_trans_close_count_session: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) in this client session
- Ndb_api_trans_close_count_slave: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this slave
- Ndb_api_trans_commit_count: Number of transactions committed by this MySQL Server (SQL node)
- Ndb_api_trans_commit_count_session: Number of transactions committed in this client session
- Ndb_api_trans_commit_count_slave: Number of transactions committed by this slave
- Ndb_api_trans_local_read_row_count_slave: Total number of rows that have been read by this slave
- Ndb_api_trans_start_count: Number of transactions started by this MySQL Server (SQL node)
- Ndb_api_trans_start_count_session: Number of transactions started in this client session
- Ndb_api_trans_start_count_slave: Number of transactions started by this slave
- Ndb_api_uk_op_count: Number of operations based on or using unique keys by this MySQL Server (SQL node)
- Ndb_api_uk_op_count_slave: Number of operations based on or using unique keys by this slave
- Ndb_api_wait_exec_complete_count: Number of times thread has been blocked while waiting for execution of an operation to complete by this MySQL Server (SQL node)
- Ndb_api_wait_exec_complete_count_session: Number of times thread has been blocked while waiting for execution of an operation to complete in this client session
- Ndb_api_wait_exec_complete_count_slave: Number of times thread has been blocked while waiting for execution of an operation to complete by this slave
- Ndb_api_wait_meta_request_count: Number of times thread has been blocked waiting for a metadata-based signal by this MySQL Server (SQL node)
- Ndb_api_wait_meta_request_count_session: Number of times thread has been blocked waiting for a metadata-based signal in this client session

- `Ndb_api_wait_nanos_count`: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this MySQL Server (SQL node)
- `Ndb_api_wait_nanos_count_session`: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes in this client session
- `Ndb_api_wait_nanos_count_slave`: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this slave
- `Ndb_api_wait_scan_result_count`: Number of times thread has been blocked while waiting for a scan-based signal by this MySQL Server (SQL node)
- `Ndb_api_wait_scan_result_count_session`: Number of times thread has been blocked while waiting for a scan-based signal in this client session
- `Ndb_api_wait_scan_result_count_slave`: Number of times thread has been blocked while waiting for a scan-based signal by this slave
- `ndb_autoincrement_prefetch_sz`: NDB auto-increment prefetch size
- `ndb_cache_check_time`: Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache
- `ndb_clear_apply_status`: Causes RESET SLAVE to clear all rows from the ndb_apply_status table; ON by default
- `Ndb_cluster_node_id`: If the server is acting as an NDB Cluster node, then the value of this variable its node ID in the cluster
- `Ndb_config_from_host`: The host name or IP address of the Cluster management server Formerly Ndb_connected_host
- `Ndb_config_from_port`: The port for connecting to Cluster management server. Formerly Ndb_connected_port
- `Ndb_conflict_fn_epoch_trans`: Number of rows that have been found in conflict by the NDB $EPOCH_TRANS() conflict detection function
- `Ndb_conflict_fn_max`: If the server is part of an NDB Cluster involved in cluster replication, the value of this variable indicates the number of times that conflict resolution based on "greater timestamp wins" has been applied
- `Ndb_conflict_fn_old`: If the server is part of an NDB Cluster involved in cluster replication, the value of this variable indicates the number of times that "same timestamp wins" conflict resolution has been applied
- `Ndb_conflict_trans_detect_iter_count`: Number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to Ndb_conflict_trans_conflict_commit_count
- `Ndb_conflict_trans_row_reject_count`: Total number of rows realigned after being found in conflict by a transactional conflict function. Includes Ndb_conflict_trans_row_conflict_count and any rows included in or dependent on conflicting transactions.
- `ndb_data_node_neighbour`: Specifies cluster data node "closest" to this MySQL Server, for transaction hinting and fully replicated tables
- `ndb_default_column_format`: Sets default row format and column format (FIXED or DYNAMIC) used for new NDB tables
- `ndb_deferred_constraints`: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.

- ndb_distribution: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)
- ndb_eventbuffer_free_percent: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by ndb_eventbuffer_max_alloc
- ndb_eventbuffer_max_alloc: Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit).
- ndb_extra_logging: Controls logging of NDB Cluster schema, connection, and data distribution events in the MySQL error log
- ndb_force_send: Forces sending of buffers to NDB immediately, without waiting for other threads
- ndb_fully_replicated: Whether new NDB tables are fully replicated
- ndb_index_stat_enable: Use NDB index statistics in query optimization
- ndb_index_stat_option: Comma-separated list of tunable options for NDB index statistics; the list should contain no spaces
- ndb_join_pushdown: Enables pushing down of joins to data nodes
- ndb_log_apply_status: Whether or not a MySQL server acting as a slave logs mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID
- ndb_log_bin: Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with --log-bin.
- ndb_log_binlog_index: Insert mapping between epochs and binary log positions into the ndb_binlog_index table. Defaults to ON. Effective only if binary logging is enabled on the server.
- ndb_log_empty_epochs: When enabled, epochs in which there were no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled
- ndb_log_empty_update: When enabled, updates which produce no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled
- ndb_log_exclusive_reads: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts
- ndb_log_orig: Whether the id and epoch of the originating server are recorded in the mysql.ndb_binlog_index table. Set using the --ndb-log-orig option when starting mysqld.
- ndb_log_transaction_id: Whether NDB transaction IDs are written into the binary log (Read-only.)
- ndb-log-update-minimal: Log updates in a minimal format.
- ndb_log_updated_only: Log complete rows (ON) or updates only (OFF)
- Ndb_number_of_data_nodes: If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster
- ndb_optimization_delay: Sets the number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables
- ndb_optimized_node_selection: Determines how an SQL node chooses a cluster data node to use as transaction coordinator
- Ndb_pushed_queries_defined: Number of joins that API nodes have attempted to push down to the data nodes

- `Ndb_pushed_queries_executed`: Number of joins successfully pushed down and executed on the data nodes
- `ndb_read_backup`: Enable read from any replica
- `ndb_recv_thread_activation_threshold`: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads)
- `ndb_recv_thread_cpu_mask`: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.
- `ndb_report_thresh_binlog_epoch_slip`: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates BUFFERED_EPOCHS_OVER_THRESHOLD event buffer status message
- `ndb_report_thresh_binlog_mem_usage`: This is a threshold on the percentage of free memory remaining before reporting binary log status
- `Ndb_scan_count`: The total number of scans executed by NDB since the cluster was last started
- `ndb_show_foreign_key_mock_tables`: Show the mock tables used to support foreign_key_checks=0
- `ndb_slave_conflict_role`: Role for slave to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when slave SQL thread is stopped. See documentation for further information.
- `Ndb_slave_max_replicated_epoch`: The most recently committed NDB epoch on this slave. When this value is greater than or equal to Ndb_conflict_last_conflict_epoch, no conflicts have yet been detected.
- `Ndb_system_name`: Configured cluster system name; empty if server not connected to NDB
- `ndb_table_no_logging`: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDBCLUSTER persists for the lifetime of the table.
- `ndb_table_temporary`: NDB tables are not persistent on disk: no schema files are created and the tables are not logged
- `ndb_use_exact_count`: Use exact row count when planning queries
- `ndb_use_transactions`: Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query
- `ndb_version`: Shows build and NDB engine version as an integer
- `ndb_version_string`: Shows build information including NDB engine version in ndb-x.y.z format
- `ndbcluster`: Enable NDB Cluster (if this version of MySQL supports it) Disabled by `--skip-ndbcluster`
- `ndbinfo_database`: The name used for the NDB information database; read only
- `ndbinfo_max_bytes`: Used for debugging only
- `ndbinfo_max_rows`: Used for debugging only
- `ndbinfo_offline`: Put the ndbinfo database into offline mode, in which no rows are returned from tables or views
- `ndbinfo_show_hidden`: Whether to show ndbinfo internal base tables in the mysql client. The default is OFF.

- `ndbinfo_table_prefix`: The prefix to use for naming ndbinfo internal base tables
- `ndbinfo_version`: The version of the ndbinfo engine; read only
- `server-id-bits`: Sets the number of least significant bits in the server_id actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. server_id must be less than 2 to the power of this value.
- `server_id_bits`: The effective value of server_id if the server was started with the --server-id-bits option set to a nondefault value
- `slave_allow_batching`: Turns update batching on and off for a replication slave
- `transaction_allow_batching`: Allows batching of statements within a transaction. Disable AUTOCOMMIT to use.

22.3.3 NDB Cluster Configuration Files

Configuring NDB Cluster requires working with two files:

- `my.cnf`: Specifies options for all NDB Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- `config.ini`: This file, sometimes known as the *global configuration file*, is read only by the NDB Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see Sections of the `config.ini` File.

Caching of configuration data. `NDB` uses *stateful configuration*. Rather than reading the global configuration file every time the management server is restarted, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following conditions is true:

- **The management server is started using the --initial option.** When `--initial` is used, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.
- **The management server is started using the --reload option.** The `--reload` option causes the management server to compare its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.
- **The management server is started using --config-cache=FALSE.** This disables `--config-cache` (enabled by default), and can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the `config.ini` file instead.
- **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

Configuration cache files. The management server by default creates configuration cache files in a directory named `mysql-cluster` in the MySQL installation directory. (If you build NDB Cluster from source on a Unix system, the default location is `/usr/local/mysql-cluster`.) This can be overridden at runtime by starting the management server with the `--configdir` option. Configuration cache files are binary files named according to the pattern `ndb_`*`node_id`*`_config.bin.`*`seq_id`*, where *`node_id`* is the management server's node ID in the cluster, and *`seq_id`* is a cache idenitifer.

Cache files are numbered sequentially using *`seq_id`*, in the order in which they are created. The management server uses the latest cache file as determined by the *`seq_id`*.

Note

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher *`seq_id`*. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--config-cache`, `--initial`, and `--reload` options for the NDB Cluster management server, see Section 22.4.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”.

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”.

22.3.3.1 NDB Cluster Configuration: Basic Example

To support NDB Cluster, you will need to update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

Note

The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (valid in MySQL 8.0)

# enable ndbcluster storage engine, and provide connection string for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connection strings, see Section 22.3.3.3, “NDB Cluster Connection Strings”.)

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (will work on all versions)

# enable ndbcluster storage engine, and provide connection string for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design*.

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional `NDB` variables that can be set in the `my.cnf` file, see NDB Cluster System Variables.

The NDB Cluster global configuration file is by convention named `config.ini` (but this is not required). If needed, it is read by `ndb_mgmd` at startup and can be placed in any location that can be read by it. The location and name of the configuration are specified using `--config-file=path_name` with `ndb_mgmd` on the command line. This option has no default value, and is ignored if `ndb_mgmd` uses the configuration cache.

The global configuration file for NDB Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (`:`) as well as the equal sign (`=`); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. To create a default value section, simply add the word `default` to the section name. For example, an `[ndbd]` section contains parameters that apply to a particular data node, whereas an `[ndbd default]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[ndbd default]` section that contains a `DataMemory` line to specify the data memory size.

Note

In some older releases of NDB Cluster, there was no default value for `NoOfReplicas`, which always had to be specified explicitly in the `[ndbd default]` section. Although this parameter now has a default value of 2, which is the recommended setting in most common usage scenarios, it is still recommended practice to set this parameter explicitly.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
```

```
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

Note

The preceding example is intended as a minimal starting configuration for purposes of familiarization with NDB Cluster , and is almost certain not to be sufficient for production settings. See Section 22.3.3.2, “Recommended Starting Configuration for NDB Cluster”, which provides a more complete example starting configuration.

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `[ndbd]` sections defining these nodes.

Note

Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

Sections of the config.ini File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[computer]`: Defines cluster hosts. This is not required to configure a viable NDB Cluster, but be may used as a convenience when setting up a large cluster. See Section 22.3.3.4, “Defining Computers in an NDB Cluster”, for more information.
- `[ndbd]`: Defines a cluster data node (`ndbd` process). See Section 22.3.3.6, “Defining NDB Cluster Data Nodes”, for details.
- `[mysqld]`: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.
- `[mgm]` or `[ndb_mgmd]`: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see Section 22.3.3.5, “Defining an NDB Cluster Management Server”.
- `[tcp]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, `[tcp]` or `[tcp default]` sections are not required to set up an NDB Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See Section 22.3.3.10, “NDB Cluster TCP/IP Connections”, for information about available TCP/IP configuration parameters and how to use them. (You may also find Section 22.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections” to be of interest in some cases.)
- `[shm]`: Defines shared-memory connections between nodes. In MySQL 8.0, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”.
- `[sci]`: Defines Scalable Coherent Interface connections between cluster data nodes. Not supported in NDB 8.0.

You can define `default` values for each section. NDB Cluster parameter names are case-insensitive, unless specified in MySQL Server `my.cnf` or `my.ini` files.

22.3.3.2 Recommended Starting Configuration for NDB Cluster

Achieving the best performance from an NDB Cluster depends on a number of factors including the following:

- NDB Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each NDB Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the NDB Cluster 's data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide a recommended base configuration.

Starting config.ini file. The following `config.ini` file is a recommended starting point for configuring a cluster running NDB Cluster 8.0:

```
# TCP PARAMETERS

[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd]
HostName=management-server-A-hostname
# NodeId=management-server-A-nodeid

[ndb_mgmd]
HostName=management-server-B-hostname
# NodeId=management-server-B-nodeid

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a NodeId for any management server, although one will be allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS

[ndbd default]
```

```
NoOfReplicas=2

# Using 2 replicas is recommended to guarantee availability of data;
# using only 1 replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to
# shut down. We do not recommend using more than 2 replicas, since 2 is
# sufficient to provide high availability, and we do not currently test
# with greater values for this parameter.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3072M
IndexMemory=384M

# The values provided for DataMemory and IndexMemory assume 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.

# ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using NDB Cluster on systems running
# Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1
# Setting these parameters allows you to take advantage of real-time scheduling
# of NDB threads to achieve increased throughput when using ndbd. They
# are not needed when using ndbmtd; in particular, you should not set
# RealTimeScheduler for ndbmtd data nodes.

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
RedoBuffer=32M

# CompressedLCP=1
# CompressedBackup=1
# Enabling CompressedLCP and CompressedBackup causes, respectively, local
checkpoint files and backup files to be compressed, which can result in a space
savings of up to 50% over noncompressed LCPs and backups.

# MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
# On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER
# threads to specific CPUs

[ndbd]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid
```

```
LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include a NodeId for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
# to 48 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS

[mysqld]
# HostName=sql-node-A-hostname
# NodeId=sql-node-A-nodeid

[mysqld]

[mysqld]

# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# “slot”; you should have at least as many of these sections in the
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (NodeId parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.
```

Recommended my.cnf options for SQL nodes. MySQL Servers acting as NDB Cluster SQL nodes must always be started with the `--ndbcluster` and `--ndb-connectstring` options, either on the command line or in `my.cnf`. In addition, set the following options for all `mysqld` processes in the cluster, unless your setup requires otherwise:

- `--ndb-use-exact-count=0`
- `--ndb-index-stat-enable=0`
- `--ndb-force-send=1`
- `--engine-condition-pushdown=1`

22.3.3.3 NDB Cluster Connection Strings

With the exception of the NDB Cluster management server (`ndb_mgmd`), each node that is part of an NDB Cluster requires a *connection string* that points to the management server's location. This connection string is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connection string is as follows:

```
[nodeid=node_id, ]host-definition[, host-definition[, ...]]

host-definition:
    host_name[:port_number]
```

`node_id` is an integer greater than or equal to 1 which identifies a node in `config.ini`. *`host_name`* is a string representing a valid Internet host name or IP address. *`port_number`* is an integer referring to a TCP/IP port number.

```
example 1 (long):    "nodeid=2,myhost1:1100,myhost2:1100,198.51.100.3:1200"
example 2 (short):   "myhost1"
```

`localhost:1186` is used as the default connection string value if none is provided. If *`port_num`* is omitted from the connection string, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see http://www.iana.org/assignments/port-numbers for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. An NDB Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

It is also possible to specify in a connection string one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connection strings is shown here:

```
[nodeid=node_id, ]
    [bind-address=host-definition, ]
    host-definition[; bind-address=host-definition]
    host-definition[; bind-address=host-definition]
    [, ...]]

host-definition:
    host_name[:port_number]
```

If a single bind address is used in the connection string *prior* to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connection string causes the node to use `198.51.100.242` regardless of the management server to which it connects:

```
bind-address=198.51.100.242, poseidon:1186, perch:1186
```

If a bind address is specified *following* a management host definition, then it is used only for connecting to that management node. Consider the following connection string:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=198.51.100.242
```

In this case, the node uses `localhost` to connect to the management server running on the host named `poseidon` and `198.51.100.242` to connect to the management server running on the host named `perch`.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, `localhost` is used for connecting to the management server running on host `poseidon`; since `198.51.100.242` is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts `perch` and `orca`:

```
bind-address=198.51.100.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connection string:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)

- It is also possible to set the connection string for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.
- For backward compatibility, two other options are available, using the same syntax:

  1. Set the `NDB_CONNECTSTRING` environment variable to contain the connection string.
  2. Write the connection string for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

  However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the `my.cnf` file for each executable.

22.3.3.4 Defining Computers in an NDB Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

  Table 22.7 This table provides type and value information for the Id computer configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	string
Default	[none]
Range	...
Restart Type	IS

  This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

  Important

  The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- `HostName`

  Table 22.8 This table provides type and value information for the HostName computer configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]
Range	...
Restart Type	N

  This is the computer's hostname or IP address.

22.3.3.5 Defining an NDB Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an

`[ndb_mgmd default]` section. `[mgm]` and `[mgm default]` are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

Note

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- `Id`

Table 22.9 This table provides type and value information for the Id management node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	[none]
Range	1 - 255
Restart Type	IS

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255, inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

Note

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId`. Although `Id` continues to be supported for backward compatibility, it now generates a warning and is subject to removal in a future version of NDB Cluster.

- `NodeId`

Table 22.10 This table provides type and value information for the NodeId management node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	[none]
Range	1 - 255
Restart Type	IS

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255 inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

Note

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes. Although the older `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used; it is also subject to removal in a future NDB Cluster release.

- `ExecuteOnComputer`

Table 22.11 This table provides type and value information for the ExecuteOnComputer management node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	name
Default	[none]
Range	...
Restart Type	S

This refers to the `Id` set for one of the computers defined in a `[computer]` section of the `config.ini` file.

Important

This parameter is deprecated, and is subject to removal in a future release. Use the `HostName` parameter instead.

- `PortNumber`

Table 22.12 This table provides type and value information for the PortNumber management node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	1186
Range	0 - 64K
Restart Type	S

This is the port number on which the management server listens for configuration requests and management commands.

- `HostName`

Table 22.13 This table provides type and value information for the HostName management node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]

Property	Value
Range	...
Restart Type	N

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- `LocationDomainId`

Table 22.14 This table provides type and value information for the LocationDomainId management node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 16
Restart Type	S

Assigns a management node to a specific availability domain (also known as an availability zone) within a cloud. By informing `NDB` which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use `NDB` transporters' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

`LocationDomainId` takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- `LogDestination`

Table 22.15 This table provides type and value information for the LogDestination management node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	{CONSOLE|SYSLOG|FILE}
Default	[see text]
Range	...
Restart Type	N

This parameter specifies where to send cluster logging information. There are three options in this regard—`CONSOLE`, `SYSLOG`, and `FILE`—with `FILE` being the default:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

  Note

  Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- `FILE` pipes the cluster log output to a regular file on the same machine. The following values can be specified:

  - `filename`: The name of the log file.

    The default log file name used in such cases is `ndb_nodeid_cluster.log`.

  - `maxsize`: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.

  - `maxfiles`: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

  The default value for the `FILE` parameter is `FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6`, where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- `ArbitrationRank`

Table 22.16 This table provides type and value information for the ArbitrationRank management node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	0-2
Default	1
Range	0 - 2
Restart Type	N

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- `0`: The node will never be used as an arbitrator.

- `1`: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.

- 2: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

You can disable arbitration completely either by setting `ArbitrationRank` to 0 on all management and SQL nodes, or by setting the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file. Setting `Arbitration` causes any settings for `ArbitrationRank` to be disregarded.

- `ArbitrationDelay`

Table 22.17 This table provides type and value information for the ArbitrationDelay management node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- `DataDir`

Table 22.18 This table provides type and value information for the DataDir management node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	path
Default	.
Range	...
Restart Type	N

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination` as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- `PortNumberStats`

Table 22.19 This table provides type and value information for the PortNumberStats management node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned

Property	Value
Default	[none]
Range	0 - 64K
Restart Type	N

This parameter specifies the port number used to obtain statistical information from an NDB Cluster management server. It has no default value.

- `Wan`

Table 22.20 This table provides type and value information for the wan management node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

Use WAN TCP setting as default.

- `HeartbeatThreadPriority`

Table 22.21 This table provides type and value information for the HeartbeatThreadPriority management node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	string
Default	[none]
Range	...
Restart Type	S

Set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
  {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of `FIFO` (first in, first out) or `RR` (round robin). The policy value is followed optionally by the priority (an integer).

- `TotalSendBufferMemory`

Table 22.22 This table provides type and value information for the TotalSendBufferMemory management node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes

Property	Value
Default	0
Range	256K - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

- `HeartbeatIntervalMgmdMgmd`

Table 22.23 This table provides type and value information for the HeartbeatIntervalMgmdMgmd management node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	1500
Range	100 - 4294967039 (0xFFFFFEFF)
Restart Type	N

Specify the interval between heartbeat messages used to determine whether another management node is on contact with this one. The management node waits after 3 of these intervals to declare the connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see Section 22.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

22.3.3.6 Defining NDB Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

`[ndbd]` and `[ndbd default]` are always used as the section names whether you are using `ndbd` or `ndbmtd` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is either one of `ExecuteOnComputer` or `HostName`; this must be defined in the local `[ndbd]` section.

The parameter `NoOfReplicas` should be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes. It is not strictly necessary to set `NoOfReplicas`, but it is good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where

present, HostName, NodeId and ExecuteOnComputer *must* be defined in the local [ndbd] section, and not in any other section of config.ini. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use K, M, or G as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, 100K means 100 × 1024 = 102400.)

Parameter names and values are case-insensitive, unless used in a MySQL Server my.cnf or my.ini file, in which case they are case sensitive.

Information about configuration parameters specific to NDB Cluster Disk Data tables can be found later in this section (see Disk Data Configuration Parameters).

All of these parameters also apply to ndbmtd (the multithreaded version of ndbd). Three additional data node configuration parameters—MaxNoOfExecutionThreads, ThreadConfig, and NoOfFragmentLogParts—apply to ndbmtd only; these have no effect when used with ndbd. For more information, see Multi-Threading Configuration Parameters (ndbmtd). See also Section 22.4.3, “ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)”.

Identifying data nodes. The NodeId or Id value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- NodeId

Table 22.24 This table provides type and value information for the NodeId data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	[none]
Range	1 - 48
Restart Type	IS

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

NodeId is the only supported parameter name to use when identifying data nodes.

- ExecuteOnComputer

Table 22.25 This table provides type and value information for the ExecuteOnComputer data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	name
Default	[none]
Range	...
Restart Type	S

This refers to the Id set for one of the computers defined in a [computer] section.

Important

This parameter is deprecated, and is subject to removal in a future release. Use the `HostName` parameter instead.

- `HostName`

Table 22.26 This table provides type and value information for the HostName data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	localhost
Range	...
Restart Type	N

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- `ServerPort`

Table 22.27 This table provides type and value information for the ServerPort data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	[none]
Range	1 - 64K
Restart Type	S

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an `[ndbd]` section or (if you need to do this for multiple data nodes) the `[ndbd default]` section of the `config.ini` file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

Note

Connections from data nodes to management nodes is done using the `ndb_mgmd` management port (the management server's `PortNumber`) so outgoing connections to that port from any data nodes should always be permitted.

- `TcpBind_INADDR_ANY`

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

- `NodeGroup`

Table 22.28 This table provides type and value information for the NodeGroup data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	
Default	[none]
Range	0 - 65536
Restart Type	IS

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the `[ndbd default]` section of the `config.ini` file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The `NodeGroup` parameter is chiefly intended for use in adding a new node group to a running NDB Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a `NodeGroup` value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see Section 22.5.15.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”.

- `LocationDomainId`

Table 22.29 This table provides type and value information for the LocationDomainId data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 16
Restart Type	S

Assigns a data node to a specific availability domain (also known as an availability zone) within a cloud. By informing `NDB` which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use `NDB` transporters' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

`LocationDomainId` takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- `NoOfReplicas`

Table 22.30 This table provides type and value information for the NoOfReplicas data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	2
Range	1 - 4
Restart Type	IS

This global parameter can be set only in the `[ndbd default]` section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

The default value for `NoOfReplicas` is 2. *This is the recommended value for most production environments*.

Important

While the maximum *possible* value for this parameter is 4, **setting `NoOfReplicas` to a value greater than 2 is not supported in production**.

Warning

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- `DataDir`

Table 22.31 This table provides type and value information for the DataDir data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	path
Default	.
Range	...

Property	Value
Restart Type	IN

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- `FileSystemPath`

Table 22.32 This table provides type and value information for the FileSystemPath data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	path
Default	DataDir
Range	...
Restart Type	IN

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.

Note

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for NDB Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- `BackupDataDir`

Table 22.33 This table provides type and value information for the BackupDataDir data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	path
Default	[see text]
Range	...
Restart Type	IN

This parameter specifies the directory in which backups are placed.

Important

The string '`/BACKUP`' is always appended to this value. For example, if you set the value of `BackupDataDir` to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the *effective* default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter.

Data Memory, Index Memory, and String Memory

`DataMemory` and `IndexMemory` are `[ndbd]` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to

understand how DataMemory and IndexMemory are used, as they usually need to be updated to reflect actual usage by the cluster.

Note

IndexMemory is deprecated, and subject to removal in a future version of NDB Cluster. See the descriptions that follow for further information.

- DataMemory

Table 22.34 This table provides type and value information for the DataMemory data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	98M
Range	1M - 1T
Restart Type	N

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by DataMemory is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate data pages, allocated from DataMemory. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

The maximum record size is 14000 bytes.

Resources assigned to DataMemory are used for storing *all* data and indexes; any memory configured as IndexMemory is automatically added to that used by DataMemory to form a common resource pool.

Currently, NDB Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get Table is full errors in MySQL client applications even when ndb_mgm -e "ALL REPORT MEMORYUSAGE" shows significant free DataMemory. This can also pose a problem with data node restarts on nodes that are heavily loaded with data.

You can control the number of partitions per local data manager for a given table by setting the NDB_TABLE option PARTITION_BALANCE to one of the values FOR_RA_BY_LDM, FOR_RA_BY_LDM_X_2, FOR_RA_BY_LDM_X_3, or FOR_RA_BY_LDM_X_4, for 1, 2, 3, or 4 partitions per LDM, respectively, when creating the table (see Section 13.1.20.11, “Setting NDB_TABLE Options”).

Note

In previous versions of NDB Cluster it was possible to create extra partitions for NDB Cluster tables and thus have more memory available for hash indexes by using the MAX_ROWS option for CREATE TABLE. While still supported for backward compatibility, using MAX_ROWS for this purpose is deprecated; you should use PARTITION_BALANCE instead.

You can also use the MinFreePct configuration parameter to help avoid problems with node restarts.

The memory space allocated by DataMemory consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in NoOfReplicas.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that DataMemory pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The DataMemory memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the DataMemory. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for DataMemory in NDB 8.0 is 98MB. The minimum value is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2−4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- IndexMemory

Table 22.35 This table provides type and value information for the IndexMemory data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	0
Range	1M - 1T
Restart Type	N

The IndexMemory parameter is deprecated (and subject to future removal); any any memory assigned to IndexMemory is allocated instead to the same pool as DataMemory, which becomes solely responsible for all resources needed for storing data and indexes in memory. In NDB 8.0, the use of IndexMemory in the cluster configuration file triggers a warning from the management server.

You can estimate the size of a hash index using this formula:

```
size  = ( (fragments * 32K) + (rows * 18) )
        * replicas
```

```
```

fragments is the number of fragments, *replicas* is the number of replicas (normally 2), and *rows* is the number of rows. If a table has one million rows, 8 fragments, and 2 replicas, the expected index memory usage is calculated as shown here:

```
((8 * 32K) + (1000000 * 18)) * 2 = ((8 * 32768) + (1000000 * 18)) * 2
= (262144 + 18000000) * 2
= 18262144 * 2 = 36524288 bytes = ~35MB
```

Index statistics for ordered indexes (when these are enabled) are stored in the `mysql.ndb_index_stat_sample` table. Since this table has a hash index, this adds to index memory usage. An upper bound to the number of rows for a given ordered index can be calculated as follows:

```
sample_size= key_size + ((key_attributes + 1) * 4)

sample_rows = IndexStatSaveSize
              * ((0.01 * IndexStatSaveScale * log2(rows * sample_size)) + 1)
              / sample_size
```

In the preceding formula, *key_size* is the size of the ordered index key in bytes, *key_attributes* is the number ot attributes in the ordered index key, and *rows* is the number of rows in the base table.

Assume that table `t1` has 1 million rows and an ordered index named `ix1` on two four-byte integers. Assume in addition that `IndexStatSaveSize` and `IndexStatSaveScale` are set to their default values (32K and 100, respectively). Using the previous 2 formulas, we can calculate as follows:

```
sample_size = 8  + ((1 + 2) * 4) = 20 bytes

sample_rows = 32K
              * ((0.01 * 100 * log2(1000000*20)) + 1)
              / 20
              = 32768 * ( (1 * ~16.811) +1) / 20
              = 32768 * ~17.811 / 20
              = ~29182 rows
```

The expected index memory usage is thus 2 * 18 * 29182 = ~1050550 bytes.

In NDB 8.0, the minimum and default vaue for this parameter is 0 (zero).

- `StringMemory`

Table 22.36 This table provides type and value information for the StringMemory data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	% or bytes
Default	25
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	S

This parameter determines how much memory is allocated for strings such as table names, and is specified in an `[ndbd]` or `[ndbd default]` section of the `config.ini` file. A value between `0` and `100` inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum

size of `.FRM` files, `MaxNoOfTriggers`, maximum column name size, and maximum default column value.

A value greater than `100` is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many `NDB` tables (1000 or more), it is possible to get Error 773 `Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error`, in which case you should increase this value. `25` (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY(a),
  UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns `a` and `b` consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in NDB Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is 2 × `DataMemory` for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` and `IndexMemory` can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire NDB Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

MinFreePct. A proportion (5% by default) of data node resources including `DataMemory` and `IndexMemory` is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the `MinFreePct` data node configuration parameter (default 5).

Table 22.37 This table provides type and value information for the MinFreePct data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	5
Range	0 - 100
Restart Type	N

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

Transaction parameters. The next few `[ndbd]` parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

`MaxDMLOperationsPerTransaction` sets the maximum number of DML operations that can be performed in a given transaction.

- `MaxNoOfConcurrentTransactions`

  Table 22.38 This table provides type and value information for the MaxNoOfConcurrentTransactions data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	4096
Range	32 - 4294967039 (0xFFFFFEFF)
Restart Type	N

  Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

  Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for the total number of transactions in the cluster can be expressed as

  ```
  TotalNoOfConcurrentTransactions =
      (maximum number of tables accessed in any single transaction + 1)
      * number of SQL nodes
  ```

  Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then 10 * 11 = 110 transaction records are required for this transaction, per MySQL server, or 110 * 10 = 1100 transaction records total. Each data node can be expected to handle TotalNoOfConcurrentTransactions / number of data nodes. For an NDB Cluster having 4 data nodes, this would mean setting

MaxNoOfConcurrentTransactions on each data node to 1100 / 4 = 275. In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's MaxNoOfConcurrentTransactions is sufficient to cover a number of transactions equal to TotalNoOfConcurrentTransactions / number of node groups. If this cluster has a single node group, then MaxNoOfConcurrentTransactions should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for MaxNoOfConcurrentTransactions should always be no more than the value of MaxNoOfConcurrentOperations.

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- MaxNoOfConcurrentOperations

Table 22.39 This table provides type and value information for the MaxNoOfConcurrentOperations data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	32K
Range	32 - 4294967039 (0xFFFFFEFF)
Restart Type	N

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set at a minimum to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to 1000000 / 4 = 250000. To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to `total number of concurrent operations / number of node groups`. (In the case where there is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of MaxNoOfConcurrentOperations should always be greater than or equal to the value of MaxNoOfConcurrentTransactions.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- `MaxNoOfLocalOperations`

Table 22.40 This table provides type and value information for the MaxNoOfLocalOperations data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	UNDEFINED
Range	32 - 4294967039 (0xFFFFFEFF)
Restart Type	N

By default, this parameter is calculated as 1.1 × `MaxNoOfConcurrentOperations`. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

- `MaxDMLOperationsPerTransaction`

Table 22.41 This table provides type and value information for the MaxDMLOperationsPerTransaction data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	operations (DML)
Default	4294967295
Range	32 - 4294967295
Restart Type	N

This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations. The minimum number of operations per transaction is 32; however, you

can set MaxDMLOperationsPerTransaction to 0 to disable any limitation on the number of DML operations per transaction. The maximum (and default) is 4294967295.

Transaction temporary storage. The next set of [ndbd] parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- MaxNoOfConcurrentIndexOperations

Table 22.42 This table provides type and value information for the MaxNoOfConcurrentIndexOperations data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	8K
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter MaxNoOfConcurrentOperations.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- MaxNoOfFiredTriggers

Table 22.43 This table provides type and value information for the MaxNoOfFiredTriggers data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	4000
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

The default value of MaxNoOfFiredTriggers is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is

short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- `TransactionBufferMemory`

Table 22.44 This table provides type and value information for the TransactionBufferMemory data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	1M
Range	1K - 4294967039 (0xFFFFFEFF)
Restart Type	N

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for `TransactionBufferMemory` is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZATTRBUF_FILESIZE` (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to 4000 × 128 bytes (500KB). A similar buffer for key information, `ZDATABUF_FILESIZE` (also in `Dbtc.hpp`) contains 4000 × 16 = 62.5KB of buffer space. `Dbtc` is the module that handles transaction coordination.

Scans and buffering. There are additional `[ndbd]` parameters in the `Dblqh` module (in `ndb/src/kernel/blocks/Dblqh/Dblqh.hpp`) that affect reads and updates. These include `ZATTRINBUF_FILESIZE`, set by default to 10000 × 128 bytes (1250KB) and `ZDATABUF_FILE_SIZE`, set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- `BatchSizePerLocalScan`

Table 22.45 This table provides type and value information for the BatchSizePerLocalScan data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	256
Range	1 - 992
Restart Type	N

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

`BatchSizePerLocalScan` has a strong connection to the `BatchSize` defined in the SQL nodes.

- `LongMessageBuffer`

Table 22.46 This table provides type and value information for the LongMessageBuffer data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	64M
Range	512K - 4294967039 (0xFFFFFEFF)
Restart Type	N

This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 64MB.

This parameter seldom needs to be changed from the default.

- `MaxFKBuildBatchSize`

Table 22.47 This table provides type and value information for the MaxFKBuildBatchSize data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	64
Range	16 - 512
Restart Type	S

Maximum scan batch size used for building foreign keys. Increasing the value set for this parameter may speed up building of foreign key builds at the expense of greater impact to ongoing traffic.

- `MaxNoOfConcurrentScans`

Table 22.48 This table provides type and value information for the MaxNoOfConcurrentScans data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	256
Range	2 - 500
Restart Type	N

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain `MaxNoOfConcurrentScans` scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is

an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of `MaxNoOfConcurrentScans` is 256. The maximum value is 500.

- `MaxNoOfLocalScans`

Table 22.49 This table provides type and value information for the MaxNoOfLocalScans data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	[see text]
Range	32 - 4294967039 (0xFFFFFEFF)
Restart Type	N

Specifies the number of local scan records if many scans are not fully parallelized. When the number of local scan records is not provided, it is calculated as shown here:

```
4 * MaxNoOfConcurrentScans * [# data nodes] + 2
```

The minimum value is 32.

- `MaxParallelCopyInstances`

Table 22.50 This table provides type and value information for the MaxParallelCopyInstances data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 64
Restart Type	S

This parameter sets the parallelization used in the copy phase of a node restart or system restart, when a node that is currently just starting is synchronised with a node that already has current data by copying over any changed records from the node that is up to date. Because full parallelism in such cases can lead to overload situations, `MaxParallelCopyInstances` provides a means to decrease it. This parameter's default value 0. This value means that the effective parallelism is equal to the number of LDM instances in the node just starting as well as the node updating it.

- `MaxParallelScansPerFragment`

Table 22.51 This table provides type and value information for the MaxParallelScansPerFragment data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	256
Range	1 - 4294967039 (0xFFFFFEFF)
Restart Type	N

It is possible to configure the maximum number of parallel scans (TUP scans and TUX scans) allowed before they begin queuing for serial handling. You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

The default value for this parameter is 256.

- MaxReorgBuildBatchSize

Table 22.52 This table provides type and value information for the MaxReorgBuildBatchSize data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	64
Range	16 - 512
Restart Type	S

Maximum scan batch size used for reorganization of table partitions. Increasing the value set for this parameter may speed up reorganization at the expense of greater impact to ongoing traffic.

- MaxUIBuildBatchSize

Table 22.53 This table provides type and value information for the MaxUIBuildBatchSize data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	64
Range	16 - 512
Restart Type	S

Maximum scan batch size used for building unique keys. Increasing the value set for this parameter may speed up such builds at the expense of greater impact to ongoing traffic.

Memory Allocation

MaxAllocate

Table 22.54 This table provides type and value information for the MaxAllocate data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	32M
Range	1M - 1G
Restart Type	N

This is the maximum size of the memory unit to use when allocating memory for tables. In cases where NDB gives Out of memory errors, but it is evident by examining the cluster logs or the output of DUMP 1000 that all available memory has not yet been used, you can increase the value of this parameter (or MaxNoOfTables, or both) to cause NDB to make sufficient memory available.

Hash Map Size

`DefaultHashMapSize`

Table 22.55 This table provides type and value information for the DefaultHashMapSize data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	LDM threads
Default	3840
Range	0 - 3840
Restart Type	N

The size of the table hash maps used by `NDB` is configurable using this parameter. `DefaultHashMapSize` can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table:

Table 22.56 DefaultHashMapSize parameters

Value	Description / Effect
`0`	Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.
`240`	Original hash map size (used in older NDB Cluster releases)
`3840`	Larger hash map size (used by default in NDB 8.0)

The original intended use for this parameter was to facilitate upgrades and especially downgrades to and from very old releases with differing default hash map sizes. This is not an issue when upgrading from NDB Cluster 7.6 to NDB Cluster 8.0.

Logging and checkpointing. The following `[ndbd]` parameters control log and checkpoint behavior.

- `FragmentLogFileSize`

  Table 22.57 This table provides type and value information for the FragmentLogFileSize data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	16M
Range	4M - 1G
Restart Type	IN

  Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when NDB Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

  For more information about fragment log files, see the description for `NoOfFragmentLogFiles`.

- `InitialNoOfOpenFiles`

Table 22.58 This table provides type and value information for the InitialNoOfOpenFiles data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	files
Default	27
Range	20 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- `InitFragmentLogFiles`

Table 22.59 This table provides type and value information for the InitFragmentLogFiles data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	[see values]
Default	SPARSE
Range	SPARSE, FULL
Restart Type	IN

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. `InitFragmentLogFiles` takes either of two values:

- `SPARSE`. Fragment log files are created sparsely. This is the default value.
- `FULL`. Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting `InitFragmentLogFiles=FULL` may help eliminate I/O errors on writes to the REDO log.

- `EnablePartialLcp`

Table 22.60 This table provides type and value information for the EnablePartialLcp data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	true
Range	...
Restart Type	N

When `true`, enable partial local checkpoints: This means that each LCP records only part of the full database, plus any records containing rows changed since the last LCP; if no rows have changed, the LCP updates only the LCP control file and does not update any data files.

If `EnablePartialLcp` is disabled (`false`), each LCP uses only a single file and writes a full checkpoint; this requires the least amount of disk space for LCPs, but increases the write load for each LCP. The default value is enabled (`true`). The proportion of space used by partiaL LCPS can be modified by the setting for the `RecoveryWork` configuration parameter.

Setting this parameter to `false` also disables the calculation of disk write speed used by the adaptive LCP control mechanism.

- `LcpScanProgressTimeout`

Table 22.61 This table provides type and value information for the LcpScanProgressTimeout data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	second
Default	60
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. This interval can be set using the `LcpScanProgressTimeout` data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.

The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

- `MaxNoOfOpenFiles`

Table 22.62 This table provides type and value information for the MaxNoOfOpenFiles data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	20 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug*.

The default value is 0. However, the minimum value to which this parameter can be set is 20.

- `MaxNoOfSavedMessages`

Table 22.63 This table provides type and value information for the MaxNoOfSavedMessages data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	25

Property	Value
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter sets the maximum number of errors written in the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

- `MaxLCPStartDelay`

Table 22.64 This table provides type and value information for the MaxLCPStartDelay data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	seconds
Default	0
Range	0 - 600
Restart Type	N

In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set `MaxLCPStartDelay`, which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

- `NoOfFragmentLogFiles`

Table 22.65 This table provides type and value information for the NoOfFragmentLogFiles data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	16
Range	3 - 4294967039 (0xFFFFFEFF)
Restart Type	IN

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until both required local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the FragmentLogFileSize parameter. In scenarios requiring a great many updates, the value for NoOfFragmentLogFiles may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (Out of log file space temporarily). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

Important

This parameter cannot be changed “on the fly”; you must restart the node using --initial. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using --initial when starting each data node).

- RecoveryWork

Table 22.66 This table provides type and value information for the RecoveryWork data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	60
Range	25 - 100
Restart Type	N

This parameter has an effect only when EnablePartialLcp is true, that is, only when partial local checkpoints are enabled. A higher value means:

- Fewer records are written for each LCP, LCPs use more space
- More work is needed during restarts

A lower value for RecoveryWork means:

- More records are written during each LCP, but LCPs require less space on disk.
- Less work during restart and thus faster restarts, at the expense of more work during normal operations

For example, setting RecoveryWork to 60 means that the total size of an LCP is roughly 1.6 times the size of the data to be checkpointed. This means that 60% more work is required during the restore phase of a restart compared to to the work done during a restart that uses full checkpoints. (This is more than compensated for during other phases of the restart such that the restart as a whole is still faster when using partial LCPs than when using full LCPs.) In order not to fill up the redo log, it is necessary to write at 1 + (1 / RecoveryWork) times the rate of data changes during checkpoints—thus, when RecoveryWork = 60, it is necessary to write at approximately 2.67 times the change rate. In order words, if changes are being written at 10 MByte per second, the checkpoint needs to be written at roughly 26.7 MByte per second.

Setting `RecoveryWork` = 40 means that only 1.4 times the total LCP size is needed (and thus the restore phase takes 10 to 15 percent less time. In this case, the checkpoint write rate is 3.5 times the rate of change.

The NDB source distribution includes a test program for simulating LCPs. `lcp_simulator.cc` can be found in `storage/ndb/src/kernel/blocks/backup/`. To compile and run it on Unix platforms, execute the commands shown here:

```
shell> gcc lcp_simulator.cc
shell> ./a.out
```

This program has no dependencies other than `stdio.h`, and does not require a connection to an NDB cluster or a MySQL server. By default, it simulates 300 LCPs (three sets of 100 LCPs, each consisting of inserts, updates, and deletes, in turn), reporting the size of the LCP after each one. You can alter the simulation by changing the values of `recovery_work`, `insert_work`, and `delete_work` in the source and recompiling. For more information, see the source of the program.

- `InsertRecoveryWork`

Table 22.67 This table provides type and value information for the InsertRecoveryWork data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	40
Range	0 - 70
Restart Type	N

Percentage of `RecoveryWork` used for inserted rows. A higher value increases the number of writes during a local checkpoint, and decreases the total size of the LCP. A lower value decreases the number of writes during an LCP, but results in more space being used for the LCP, which means that recovery takes longer. This parameter has an effect only when `EnablePartialLcp` is true, that is, only when partial local checkpoints are enabled.

- `EnableRedoControl`

Table 22.68 This table provides type and value information for the EnableRedoControl data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	true
Range	...
Restart Type	N

Enable adaptive checkpointing speed for controlling redo log usage. Set to `false` to disable (the default). Setting `EnablePartialLcp` to `false` also disables the adaptive calculation.

When enabled, `EnableRedoControl` allows the data nodes greater flexibility with regard to the rate at which they write LCPs to disk. More specifically, enabling this parameter means that higher write rates can be employed, so that LCPs can complete and Redo logs be trimmed more quickly, thereby reducing recovery time and disk space requirements. This functionality allows data nodes to make better use of the higher rate of I/O and greater bandwidth available from modern solid-

state storage devices and protocols, such as solid-state drives (SSDs) using Non-Volatile Memory Express (NVMe).

The parameter currently defaults to `false` (disabled) due to the fact that `NDB` is still deployed widely on systems whose I/O or bandwidth is constrained relative to those employing solid-state technology, such as those using conventional hard disks (HDDs). In settings such as these, the `EnableRedoControl` mechanism can easily cause the I/O subsystem to become saturated, increasing wait times for data node input and output. In particular, this can cause issues with NDB Disk Data tables which have tablespaces or log file groups sharing a constrained IO subsystem with data node LCP and redo log files; such problems potentially include node or cluster failure due to GCP stop errors.

Metadata objects. The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters.

Note

These act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- `MaxNoOfAttributes`

Table 22.69 This table provides type and value information for the MaxNoOfAttributes data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	1000
Range	32 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like `MaxNoOfTables`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfAttributes` attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the NDB Cluster table having the greatest number of attributes (*`greatest_number_of_attributes`*) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` would be `6 * greatest_number_of_attributes = 600`.

You should also estimate the average number of attributes per table and multiply this by `MaxNoOfTables`. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of `MaxNoOfTables` and test it again.

- `MaxNoOfTables`

Table 22.70 This table provides type and value information for the MaxNoOfTables data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	128
Range	8 - 20320
Restart Type	N

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like `MaxNoOfAttributes`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfTables` tables.)

For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- `MaxNoOfOrderedIndexes`

Table 22.71 This table provides type and value information for the MaxNoOfOrderedIndexes data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	128
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. `MaxNoOfOrderedIndexes` sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- `MaxNoOfUniqueHashIndexes`

Table 22.72 This table provides type and value information for the MaxNoOfUniqueHashIndexes data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	64
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the `USING HASH` option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- `MaxNoOfTriggers`

Table 22.73 This table provides type and value information for the MaxNoOfTriggers data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	768
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- `MaxNoOfSubscriptions`

Table 22.74 This table provides type and value information for the MaxNoOfSubscriptions data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

Each `NDB` table in an NDB Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for `MaxNoOfSubscriptions` is 0, which is treated as equal to `MaxNoOfTables`. Each subscription consumes 108 bytes.

- `MaxNoOfSubscribers`

Table 22.75 This table provides type and value information for the MaxNoOfSubscribers data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter is of interest only when using NDB Cluster Replication. The default value is 0, which is treated as `2 * MaxNoOfTables`; that is, there is one subscription per `NDB` table for each of two MySQL servers (one acting as the replication master and the other as the slave). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-master replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of `mysqld` processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three NDB Cluster s, with one `mysqld` attached to each cluster, and each of these `mysqld` processes acts as a master and as a slave, you should set `MaxNoOfSubscribers` equal to `3 * MaxNoOfTables`.

For more information, see Section 22.6, “NDB Cluster Replication”.

- `MaxNoOfConcurrentSubOperations`

Table 22.76 This table provides type and value information for the MaxNoOfConcurrentSubOperations data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	256
Range	0 - 4294967039 (0xFFFFFEFF)

Property	Value
Restart Type	N

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

Boolean parameters. The behavior of data nodes is also affected by a set of `[ndbd]` parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

- `CompressedBackup`

Table 22.77 This table provides type and value information for the CompressedBackup data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

Enabling this parameter causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

Important

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

- `CompressedLCP`

Table 22.78 This table provides type and value information for the CompressedLCP data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

Setting this parameter to `1` causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

Important

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

- `CrashOnCorruptedTuple`

Table 22.79 This table provides type and value information for the CrashOnCorruptedTuple data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	true
Range	true, false
Restart Type	S

When this parameter is enabled (the default), it forces a data node to shut down whenever it encounters a corrupted tuple.

- `Diskless`

Table 22.80 This table provides type and value information for the Diskless data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	true|false (1|0)
Default	false
Range	true, false
Restart Type	IS

It is possible to specify NDB Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

Important

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

`Diskless` is disabled by default.

- `LateAlloc`

Table 22.81 This table provides type and value information for the LateAlloc data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13

Property	Value
Type or units	numeric
Default	1
Range	0 - 1
Restart Type	N

Allocate memory for this data node after a connection to the management server has been established. Enabled by default.

- `LockPagesInMainMemory`

Table 22.82 This table provides type and value information for the LockPagesInMainMemory data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	0
Range	0 - 2
Restart Type	N

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

This parameter takes one of the integer values `0`, `1`, or `2`, which act as shown in the following list:

- `0`: Disables locking. This is the default value.
- `1`: Performs the lock after allocating memory for the process.
- `2`: Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. (`LockPagesInMainMemory` uses the `mlockall` function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by `max locked memory`. For more information, see `ulimit -l` and http://linux.die.net/man/2/mlock).

Note

In older NDB Cluster releases, this parameter was a Boolean. `0` or `false` was the default setting, and disabled locking. `1` or `true` enabled locking of the process after its memory was allocated. NDB Cluster 8.0 treats `true` or `false` for the value of this parameter as an error.

Important

Beginning with `glibc` 2.10, `glibc` uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The `glibc` behavior is intended to be configurable via the `MALLOC_ARENA_MAX` environment variable, but a bug in this mechanism prior to `glibc` 2.16 meant that this variable could not be set to less than 8, so

that the wasted memory could not be reclaimed. (Bug #15907219; see also http://sourceware.org/bugzilla/show_bug.cgi?id=13137 for more information concerning this issue.)

One possible workaround for this problem is to use the `LD_PRELOAD` environment variable to preload a `jemalloc` memory allocation library to take the place of that supplied with `glibc`.

- `ODirect`

Table 22.83 This table provides type and value information for the ODirect data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

Enabling this parameter causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage. When using NDB Cluster on Linux, enable `ODirect` if you are using a 2.6 or later kernel.

`ODirect` is disabled by default.

- `ODirectSyncFlag`

Table 22.84 This table provides type and value information for the ODirectSyncFlag data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

When this parameter is enabled, redo log writes are performed such that each completed file system write is handled as a call to `fsync`. The setting for this parameter is ignored if at least one of the following conditions is true:

- `ODirect` is not enabled.
- `InitFragmentLogFiles` is set to `SPARSE`.

Disabled by default.

- `RestartOnErrorInsert`

Table 22.85 This table provides type and value information for the RestartOnErrorInsert data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	error code

Property	Value
Default	2
Range	0 - 4
Restart Type	N

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- `StopOnError`

Table 22.86 This table provides type and value information for the StopOnError data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	1
Range	0, 1
Restart Type	N

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is 1; this means that, by default, an error causes the data node process to halt.

When an error is encountered and `StopOnError` is 0, the data node process is restarted.

Users of MySQL Cluster Manager should note that, when `StopOnError` equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See Starting and Stopping the Agent on Linux, for more information.

- `UseShm`

Table 22.87 This table provides type and value information for the UseShm shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	S

Enable a shared memory connection between this data node and the API node also running on this host. Set to 1 to enable.

Controlling Timeouts, Intervals, and Disk Paging

There are a number of `[ndbd]` parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- `TimeBetweenWatchDogCheck`

Table 22.88 This table provides type and value information for the TimeBetweenWatchDogCheck data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	6000
Range	70 - 4294967039 (0xFFFFFEFF)
Restart Type	N

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- `TimeBetweenWatchDogCheckInitial`

Table 22.89 This table provides type and value information for the TimeBetweenWatchDogCheckInitial data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	6000
Range	70 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This is similar to the `TimeBetweenWatchDogCheck` parameter, except that `TimeBetweenWatchDogCheckInitial` controls the amount of time that passes between execution checks inside a storage node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

- `StartPartialTimeout`

Table 22.90 This table provides type and value information for the StartPartialTimeout data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	30000
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- `StartPartitionedTimeout`

Table 22.91 This table provides type and value information for the StartPartitionedTimeout data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	60000
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

If the cluster is ready to start after waiting for `StartPartialTimeout` milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If `StartPartitionedTimeout` is set to 0, the cluster waits indefinitely.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default timeout is 60000 milliseconds (60 seconds).

- `StartFailureTimeout`

Table 22.92 This table provides type and value information for the StartFailureTimeout data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10−15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- `StartNoNodeGroupTimeout`

Table 22.93 This table provides type and value information for the StartNoNodeGroupTimeout data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	15000

Property	Value
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

When a data node is configured with `Nodegroup = 65536`, is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodegroupTimeout` milliseconds, then treats such nodes as though they had been added to the list passed to the `--nowait-nodes` option, and starts. The default value is `15000` (that is, the management server waits 15 seconds). Setting this parameter equal to `0` means that the cluster waits indefinitely.

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

See Section 22.5.15, “Adding NDB Cluster Data Nodes Online”, for more information.

- `HeartbeatIntervalDbDb`

Table 22.94 This table provides type and value information for the HeartbeatIntervalDbDb data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	5000
Range	10 - 4294967039 (0xFFFFFEFF)
Restart Type	N

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. Heartbeats cannot be disabled.

After missing four heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is five times the heartbeat interval.

The default heartbeat interval is 5000 milliseconds (5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also Network communication and latency, as well as the description of the `ConnectCheckIntervalDelay` configuration parameter.

- `HeartbeatIntervalDbApi`

Table 22.95 This table provides type and value information for the HeartbeatIntervalDbApi data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	1500
Range	100 - 4294967039 (0xFFFFFEFF)
Restart Type	N

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for `HeartbeatIntervalDbDb`.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see Network communication and latency.

- `HeartbeatOrder`

Table 22.96 This table provides type and value information for the HeartbeatOrder data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	0
Range	0 - 65535
Restart Type	S

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster. .

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers `host1` and `host2`, and that these data nodes make up 2 node groups, as shown in the following table:

Table 22.97 Four data nodes A, B, C, D running on two host computers host1, host2; each data node belongs to one of two node groups.

Node Group	Nodes Running on `host1`	Nodes Running on `host2`
Node Group 0:	Node A	Node B
Node Group 1:	Node C	Node D

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The `HeartbeatOrder` configuration parameter makes the order of heartbeat transmission user-configurable. The default value for `HeartbeatOrder` is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by `NDB`. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their `HeartbeatOrder` values from lowest to highest (and then directly from the data node having the highest `HeartbeatOrder` to the data node having the lowest value, to complete the circle). The values need not be consecutive; for example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the `HeartbeatOrder` values as shown here:

Table 22.98 HeartbeatOrder values to force a heartbeat transition order of A->B->D->C->A.

Node	`HeartbeatOrder` Value
A	10
B	20
C	30
D	25

To use this parameter to change the heartbeat transmission order in a running NDB Cluster, you must first set `HeartbeatOrder` for each data node in the cluster in the global configuration (`config.ini`) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts*.

You can use `DUMP 908` to observe the effect of this parameter in the data node logs.

- `ConnectCheckIntervalDelay`

Table 22.99 This table provides type and value information for the ConnectCheckIntervalDelay data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter enables connection checking between data nodes after one of them has failed heartbeat checks for 5 intervals of up to `HeartbeatIntervalDbDb` milliseconds.

Such a data node that further fails to respond within an interval of `ConnectCheckIntervalDelay` milliseconds is considered suspect, and is considered dead after two such intervals. This can be useful in setups with known latency issues.

The default value for this parameter is 0 (disabled).

- `TimeBetweenLocalCheckpoints`

Table 22.100 This table provides type and value information for the TimeBetweenLocalCheckpoints data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	number of 4-byte words, as a base-2 logarithm
Default	20
Range	0 - 31
Restart Type	N

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB (4×2^{20}) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting `TimeBetweenLocalCheckpoints` to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- `TimeBetweenGlobalCheckpoints`

Table 22.101 This table provides type and value information for the TimeBetweenGlobalCheckpoints data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	2000
Range	20 - 32000
Restart Type	N

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- `TimeBetweenGlobalCheckpointsTimeout`

Table 22.102 This table provides type and value information for the TimeBetweenGlobalCheckpointsTimeout data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	120000
Range	10 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter defines the minimum timeout between global checkpoints. The default is 120000 milliseconds.

- `TimeBetweenEpochs`

Table 22.103 This table provides type and value information for the TimeBetweenEpochs data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	100
Range	0 - 32000
Restart Type	N

This parameter defines the interval between synchronization epochs for NDB Cluster Replication. The default value is 100 milliseconds.

`TimeBetweenEpochs` is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

- `TimeBetweenEpochsTimeout`

Table 22.104 This table provides type and value information for the TimeBetweenEpochsTimeout data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	0
Range	0 - 256000
Restart Type	N

This parameter defines a timeout for synchronization epochs for NDB Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. The default value is 0; in other words, the timeout is disabled.

`TimeBetweenEpochsTimeout` is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

- `MaxBufferedEpochs`

Table 22.105 This table provides type and value information for the MaxBufferedEpochs data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	epochs
Default	100
Range	0 - 100000
Restart Type	N

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the `NDB` client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

- `MaxBufferedEpochBytes`

Table 22.106 This table provides type and value information for the MaxBufferedEpochBytes data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	26214400
Range	26214400 (0x01900000) - 4294967039 (0xFFFFFEFF)
Restart Type	N

The total number of bytes allocated for buffering epochs by this node.

- `TimeBetweenInactiveTransactionAbortCheck`

Table 22.107 This table provides type and value information for the TimeBetweenInactiveTransactionAbortCheck data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	1000
Range	1000 - 4294967039 (0xFFFFFEFF)
Restart Type	N

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- `TransactionInactiveTimeout`

Table 22.108 This table provides type and value information for the TransactionInactiveTimeout data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	[see text]
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is `4G` (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. Setting it to 0 means that the application never times out. The unit is milliseconds.

- `TransactionDeadlockDetectionTimeout`

Table 22.109 This table provides type and value information for the TransactionDeadlockDetectionTimeout data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	1200
Range	50 - 4294967039 (0xFFFFFEFF)
Restart Type	N

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. This parameter sets the amount of time that the transaction can spend executing within a data node, that is, the time that the transaction coordinator waits for each data node participating in the transaction to execute a request.

A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

The minimum for this parameter is 50 milliseconds.

- `DiskSyncSize`

Table 22.110 This table provides type and value information for the DiskSyncSize data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	4M
Range	32K - 4294967039 (0xFFFFFEFF)
Restart Type	N

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is *not* intended to take the place of `TimeBetweenLocalCheckpoints`.

Note

When `ODirect` is enabled, it is not necessary to set `DiskSyncSize`; in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

- `MaxDiskWriteSpeed`

Table 22.111 This table provides type and value information for the MaxDiskWriteSpeed data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	20M
Range	1M - 1024G
Restart Type	S

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when no restarts (by this data node or any other data node) are taking place in this NDB Cluster.

For setting the maximum rate of disk writes allowed while this data node is restarting, use `MaxDiskWriteSpeedOwnRestart`. For setting the maximum rate of disk writes allowed while other data nodes are restarting, use `MaxDiskWriteSpeedOtherNodeRestart`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

- `MaxDiskWriteSpeedOtherNodeRestart`

Table 22.112 This table provides type and value information for the MaxDiskWriteSpeedOtherNodeRestart data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	50M

Property	Value
Range	1M - 1024G
Restart Type	S

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when one or more data nodes in this NDB Cluster are restarting, other than this node.

For setting the maximum rate of disk writes allowed while this data node is restarting, use `MaxDiskWriteSpeedOwnRestart`. For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use `MaxDiskWriteSpeed`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

- `MaxDiskWriteSpeedOwnRestart`

Table 22.113 This table provides type and value information for the MaxDiskWriteSpeedOwnRestart data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	200M
Range	1M - 1024G
Restart Type	S

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations while this data node is restarting.

For setting the maximum rate of disk writes allowed while other data nodes are restarting, use `MaxDiskWriteSpeedOtherNodeRestart`. For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use `MaxDiskWriteSpeed`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

- `MinDiskWriteSpeed`

Table 22.114 This table provides type and value information for the MinDiskWriteSpeed data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	10M
Range	1M - 1024G
Restart Type	S

Set the minimum rate for writing to disk, in bytes per second, by local checkpoints and backup operations.

The maximum rates of disk writes allowed for LCPs and backups under various conditions are adjustable using the parameters `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOwnRestart`, and `MaxDiskWriteSpeedOtherNodeRestart`. See the descriptions of these parameters for more information.

- `ArbitrationTimeout`

Table 22.115 This table provides type and value information for the ArbitrationTimeout data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	7500
Range	10 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 7500 milliseconds (7.5 seconds).

- `Arbitration`

Table 22.116 This table provides type and value information for the Arbitration data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	enumeration
Default	Default
Range	Default, Disabled, WaitExternal
Restart Type	N

The `Arbitration` parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the `ArbitrationRank` settings for the management and API nodes. This is the default value.
- **Disabled.** Setting `Arbitration = Disabled` in the `[ndbd default]` section of the `config.ini` file to accomplishes the same task as setting `ArbitrationRank` to 0 on all management and API nodes. When `Arbitration` is set in this way, any `ArbitrationRank` settings are ignored.
- **WaitExternal.** The `Arbitration` parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by `ArbitrationTimeout` has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting `Arbitration = WaitExternal` in the `[ndbd default]` section of the `config.ini` file. For best results with the `WaitExternal` setting, it is recommended that `ArbitrationTimeout` be 2 times as long as the interval required by the external cluster manager to perform arbitration.

Important

This parameter should be used only in the `[ndbd default]` section of the cluster configuration file. The behavior of the cluster is unspecified when `Arbitration` is set to different values for individual data nodes.

- `RestartSubscriberConnectTimeout`

Table 22.117 This table provides type and value information for the RestartSubscriberConnectTimeout data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	ms
Default	12000
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	S

This parameter determines the time that a data node waits for subscribing API nodes to connect. Once this timeout expires, any “missing” API nodes are disconnected from the cluster. To disable this timeout, set `RestartSubscriberConnectTimeout` to 0.

While this parameter is specified in milliseconds, the timeout itself is resolved to the next-greatest whole second.

Buffering and logging. Several `[ndbd]` configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the `NDB` storage engine's file system abstraction layer.

- `UndoIndexBuffer`

Table 22.118 This table provides type and value information for the UndoIndexBuffer data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	2M
Range	1M - 4294967039 (0xFFFFFEFF)
Restart Type	N

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The `NDB` storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this

buffer is too small, the NDB storage engine issues internal error code 677 (`Index UNDO buffers overloaded`).

Important

It is not safe to decrease the value of this parameter during a rolling restart.

- `UndoDataBuffer`

Table 22.119 This table provides type and value information for the UndoDataBuffer data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	16M
Range	1M - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (`Data UNDO buffers overloaded`).

Important

It is not safe to decrease the value of this parameter during a rolling restart.

- `RedoBuffer`

Table 22.120 This table provides type and value information for the RedoBuffer data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	32M
Range	1M - 4294967039 (0xFFFFFEFF)
Restart Type	N

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the

data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

`RedoBuffer` sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.

If this buffer is too small, the `NDB` storage engine issues error code 1221 (`REDO log buffers overloaded`). For this reason, you should exercise care if you attempt to decrease the value of `RedoBuffer` as part of an online change in the cluster's configuration.

`ndbmtd` allocates a separate buffer for each LDM thread (see `ThreadConfig`). For example, with 4 LDM threads, an `ndbmtd` data node actually has 4 buffers and allocates `RedoBuffer` bytes to each one, for a total of `4 * RedoBuffer` bytes.

- `EventLogBufferSize`

Table 22.121 This table provides type and value information for the EventLogBufferSize data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	8192
Range	0 - 64K
Restart Type	S

Controls the size of the circular buffer used for NDB log events within data nodes.

Controlling log messages. In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- `LogLevelStartup`

Table 22.122 This table provides type and value information for the LogLevelStartup data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	1
Range	0 - 15
Restart Type	N

The reporting level for events generated during startup of the process.

The default level is 1.

- `LogLevelShutdown`

Table 22.123 This table provides type and value information for the LogLevelShutdown data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 15
Restart Type	N

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- `LogLevelStatistic`

Table 22.124 This table provides type and value information for the LogLevelStatistic data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 15
Restart Type	N

The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.

The default level is 0.

- `LogLevelCheckpoint`

Table 22.125 This table provides type and value information for the LogLevelCheckpoint data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	log level
Default	0
Range	0 - 15
Restart Type	N

The reporting level for events generated by local and global checkpoints.

The default level is 0.

- `LogLevelNodeRestart`

Table 22.126 This table provides type and value information for the LogLevelNodeRestart data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 15
Restart Type	N

The reporting level for events generated during node restart.

The default level is 0.

- `LogLevelConnection`

Table 22.127 This table provides type and value information for the LogLevelConnection data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 15
Restart Type	N

The reporting level for events generated by connections between cluster nodes.

The default level is 0.

- `LogLevelError`

Table 22.128 This table provides type and value information for the LogLevelError data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 15
Restart Type	N

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- `LogLevelCongestion`

Table 22.129 This table provides type and value information for the LogLevelCongestion data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13

Property	Value
Type or units	level
Default	0
Range	0 - 15
Restart Type	N

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- `LogLevelInfo`

Table 22.130 This table provides type and value information for the LogLevelInfo data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 15
Restart Type	N

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- `MemReportFrequency`

Table 22.131 This table provides type and value information for the MemReportFrequency data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of the `DataMemory` and `IndexMemory`, respectively, set in the `config.ini` file. For example, if `DataMemory` is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

`MemReportFrequency` is not a required parameter. If used, it can be set for all cluster data nodes in the `[ndbd default]` section of `config.ini`, and can also be set or overridden for individual data nodes in the corresponding `[ndbd]` sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory

usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in Section 22.5.6.2, “NDB Cluster Log Events”.

- `StartupStatusReportFrequency`

Table 22.132 This table provides type and value information for the StartupStatusReportFrequency data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	seconds
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

When a data node is started with the `--initial`, it initializes the redo log file during Start Phase 4 (see Section 22.5.1, “Summary of NDB Cluster Start Phases”). When very large values are set for `NoOfFragmentLogFiles`, `FragmentLogFileSize`, or both, this initialization can take a long time.You can force reports on the progress of this process to be logged periodically, by means of the `StartupStatusReportFrequency` configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 1: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15557
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 2: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15570
```

These reports are logged each `StartupStatusReportFrequency` seconds during Start Phase 4. If `StartupStatusReportFrequency` is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

Data Node Debugging Parameters

The following parameters are intended for use during testing or debugging of data nodes, and not for use in production.

- `DictTrace`

Table 22.133 This table provides type and value information for the DictTrace data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	undefined
Range	0 - 100
Restart Type	N

It is possible to cause logging of traces for events generated by creating and dropping tables using `DictTrace`. This parameter is useful only in debugging NDB kernel code. `DictTrace` takes an integer value. 0 is the default, and means no logging is performed; 1 enables trace logging, and 2 enables logging of additional `DBDICT` debugging output.

- `WatchdogImmediateKill`

Table 22.134 This table provides type and value information for the WatchDogImmediateKill data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	S

You can cause threads to be killed immediately whenever watchdog issues occur by enabling the `WatchdogImmediateKill` data node configuration parameter. This parameter should be used only when debugging or troubleshooting, to obtain trace files reporting exactly what was occurring the instant that execution ceased.

Backup parameters. The `[ndbd]` parameters discussed in this section define memory buffers set aside for execution of online backups.

- `BackupDataBufferSize`

Table 22.135 This table provides type and value information for the BackupDataBufferSize data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	16M
Range	512K - 4294967039 (0xFFFFFEFF)
Restart Type	N

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as `BackupWriteSize`, the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value for this parameter is 16MB. The minimum is 512K.

- `BackupDiskWriteSpeedPct`

Table 22.136 This table provides type and value information for the BackupDiskWriteSpeedPct data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	percent
Default	50
Range	0 - 90
Restart Type	N

During normal operation, data nodes attempt to maximize the disk write speed used for local checkpoints and backups while remaining within the bounds set by `MinDiskWriteSpeed` and `MaxDiskWriteSpeed`. Disk write throttling gives each LDM thread an equal share of the total

budget. This allows parallel LCPs to take place without exceeding the disk I/O budget. Because a backup is executed by only one LDM thread, this effectively caused a budget cut, resulting in longer backup completion times, and—if the rate of change is sufficiently high—in failure to complete the backup when the backup log buffer fill rate is higher than the achievable write rate.

This problem can be addressed by using the `BackupDiskWriteSpeedPct` configuration parameter, which takes a value in the range 0-90 (inclusive) which is interpreted as the percentage of the node's maximum write rate budget that is reserved prior to sharing out the remainder of the budget among LDM threads for LCPs. The LDM thread running the backup receives the whole write rate budget for the backup, plus its (reduced) share of the write rate budget for local checkpoints.

The default value for this parameter is 50 (interpreted as 50%).

- `BackupLogBufferSize`

Table 22.137 This table provides type and value information for the BackupLogBufferSize data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	16M
Range	2M - 4294967039 (0xFFFFFEFF)
Restart Type	N

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See Section 22.5.3.3, “Configuration for NDB Cluster Backups”.

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- `BackupMemory`

Table 22.138 This table provides type and value information for the BackupMemory data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	32M
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter is deprecated, and subject to removal in a future version of NDB Cluster. Any setting made for it is ignored.

- `BackupReportFrequency`

Table 22.139 This table provides type and value information for the BackupReportFrequency data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	seconds
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see Logging and checkpointing). `BackupReportFrequency` represents the time in seconds between backup status reports.

The default value is 0.

- `BackupWriteSize`

Table 22.140 This table provides type and value information for the BackupWriteSize data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	256K
Range	32K - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 256KB.

- `BackupMaxWriteSize`

Table 22.141 This table provides type and value information for the BackupMaxWriteSize data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	1M
Range	256K - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 1MB.

Note

The location of the backup files is determined by the `BackupDataDir` data node configuration parameter.

Additional requirements. When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

NDB Cluster Realtime Performance Parameters

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

Note

To make use of these parameters, the data node process must be run as system root.

- `LockExecuteThreadToCPU`

Table 22.142 This table provides type and value information for the LockExecuteThreadToCPU data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	set of CPU IDs
Default	0
Range	...
Restart Type	N

When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. When used with `ndbmtd`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).

The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter. You can obtain more finely-grained control of this type using `ThreadConfig`.

`LockExecuteThreadToCPU` has no default value.

- `LockMaintThreadsToCPU`

Table 22.143 This table provides type and value information for the LockMaintThreadsToCPU data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	CPU ID
Default	0
Range	0 - 64K

Property	Value
Restart Type	N

This parameter specifies the ID of the CPU assigned to handle `NDBCLUSTER` maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). *There is no default value*.

- `RealtimeScheduler`

Table 22.144 This table provides type and value information for the RealtimeScheduler data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

Setting this parameter to 1 enables real-time scheduling of data node threads.

The default is 0 (scheduling disabled).

- `SchedulerExecutionTimer`

Table 22.145 This table provides type and value information for the SchedulerExecutionTimer data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	µs
Default	50
Range	0 - 11000
Restart Type	N

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 µsec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

- `SchedulerResponsiveness`

Table 22.146 This table provides type and value information for the SchedulerResponsiveness data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	5
Range	0 - 10
Restart Type	S

Set the balance in the NDB scheduler between speed and throughput. This parameter takes an integer whose value is in the range 0-10 inclusive, with 5 as the default. Higher values provide better response times relative to throughput. Lower values provide increased throughput at the expense of longer response times.

- SchedulerSpinTimer

Table 22.147 This table provides type and value information for the SchedulerSpinTimer data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	µs
Default	0
Range	0 - 500
Restart Type	N

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

The default value is 0.

- BuildIndexThreads

Table 22.148 This table provides type and value information for the BuildIndexThreads data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	128
Range	0 - 128
Restart Type	S

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running ndb_restore --rebuild-indexes. It is supported only when there is more than one fragment for the table per data node (for example, when COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_LDM_X_2" is used with CREATE TABLE).

Setting this parameter to 0 (the default) disables multithreaded building of ordered indexes.

This parameter is supported when using ndbd or ndbmtd.

You can enable multithreaded builds during data node initial restarts by setting the TwoPassInitialNodeRestartCopy data node configuration parameter to TRUE.

- TwoPassInitialNodeRestartCopy

Table 22.149 This table provides type and value information for the TwoPassInitialNodeRestartCopy data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean

Property	Value
Default	true
Range	true, false
Restart Type	N

Multithreaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to `true` (the default value), which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` to a nonzero value.

- `Numa`

Table 22.150 This table provides type and value information for the Numa data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	1
Range	...
Restart Type	N

This parameter determines whether Non-Uniform Memory Access (NUMA) is controlled by the operating system or by the data node process, whether the data node uses `ndbd` or `ndbmtd`. By default, `NDB` attempts to use an interleaved NUMA memory allocation policy on any data node where the host operating system provides NUMA support.

Setting `Numa = 0` means that the datanode process does not itself attempt to set a policy for memory allocation, and permits this behavior to be determined by the operating system, which may be further guided by the separate `numactl` tool. That is, `Numa = 0` yields the system default behavior, which can be customised by `numactl`. For many Linux systems, the system default behavior is to allocate socket-local memory to any given process at allocation time. This can be problematic when using `ndbmtd`; this is because `nbdmtd` allocates all memory at startup, leading to an imbalance, giving different access speeds for different sockets, especially when locking pages in main memory.

Setting `Numa = 1` means that the data node process uses `libnuma` to request interleaved memory allocation. (This can also be accomplished manually, on the operating system level, using `numactl`.) Using interleaved allocation in effect tells the data node process to ignore non-uniform memory access but does not attempt to take any advantage of fast local memory; instead, the data node process tries to avoid imbalances due to slow remote memory. If interleaved allocation is not desired, set `Numa` to 0 so that the desired behavior can be determined on the operating system level.

The `Numa` configuration parameter is supported only on Linux systems where `libnuma.so` is available.

Multi-Threading Configuration Parameters (ndbmtd). `ndbmtd` runs by default as a single-threaded process and must be configured to use multiple threads, using either of two methods, both of which require setting configuration parameters in the `config.ini` file. The first method is simply to set an appropriate value for the `MaxNoOfExecutionThreads` configuration parameter. A second method, makes it possible to set up more complex rules for `ndbmtd` multithreading using `ThreadConfig`. The next few paragraphs provide information about these parameters and their use with multithreaded data nodes.

- `MaxNoOfExecutionThreads`

Table 22.151 This table provides type and value information for the MaxNoOfExecutionThreads multi-threaded data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	2
Range	2 - 72
Restart Type	S

This parameter directly controls the number of execution threads used by `ndbmtd`, up to a maximum of 72. Although this parameter is set in `[ndbd]` or `[ndbd default]` sections of the `config.ini` file, it is exclusive to `ndbmtd` and does not apply to `ndbd`.

Setting `MaxNoOfExecutionThreads` sets the number of threads for each type as determined by a matrix in the file `storage/ndb/src/kernel/vm/mt_thr_config.cpp`. This table shows these numbers of threads for possible values of `MaxNoOfExecutionThreads`.

Table 22.152 MaxNoOfExecutionThreads values and the corresponding number of threads by thread type (LQH, TC, Send, Receive).

`MaxNoOfExecutionThreads` Value	LDM Threads	TC Threads	Send Threads	Receive Threads
0 .. 3	1	0	0	1
4 .. 6	2	0	0	1
7 .. 8	4	0	0	1
9	4	2	0	1
10	4	2	1	1
11	4	3	1	1

68	32	18	8	8
69	32	18	8	9

MaxNoOfExecutionThreads Value	LDM Threads	TC Threads	Send Threads	Receive Threads
70	32	19	8	9
71	32	20	8	9
72	32	20	8	10

There is always one SUMA (replication) thread.

`NoOfFragmentLogParts` should be set equal to the number of LDM threads used by `ndbmtd`, as determined by the setting for this parameter. This ratio should not be any greater than 4:1; a configuration in which this is the case is specifically disallowed.

The number of LDM threads also determines the number of partitions used by an `NDB` table that is not explicitly partitioned; this is the number of LDM threads times the number of data nodes in the cluster. (If `ndbd` is used on the data nodes rather than `ndbmtd`, then there is always a single LDM thread; in this case, the number of partitions created automatically is simply equal to the number of data nodes. See Section 22.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”, for more information.

Adding large tablespaces for Disk Data tables when using more than the default number of LDM threads may cause issues with resource and CPU usage if the disk page buffer is insufficiently large; see the description of the `DiskPageBufferMemory` configuration parameter, for more information.

The thread types are described later in this section (see `ThreadConfig`).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error `Error line number: Illegal value value for parameter MaxNoOfExecutionThreads`.

For `MaxNoOfExecutionThreads`, a value of 0 or 1 is rounded up internally by `NDB` to 2, so that 2 is considered this parameter's default and minimum value.

`MaxNoOfExecutionThreads` is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings provided, or to bind threads to CPUs, you should use `ThreadConfig` instead, which allows you to allocate each thread directly to a desired type, CPU, or both.

The multithreaded data node process always spawns, at a minimum, the threads listed here:

- 1 local query handler (LDM) thread
- 1 receive thread
- 1 subscription manager (SUMA or replication) thread

For a `MaxNoOfExecutionThreads` value of 8 or less, no TC threads are created, and TC handling is instead performed by the main thread.

Changing the number of LDM threads normally requires a system restart, whether it is changed using this parameter or `ThreadConfig`, but it is possible to effect the change using a node initial restart (*NI*) provided the following two conditions are met:

- Each LDM thread handles a maximum of 8 fragments, and
- The total number of table fragments is an integer multiple of the number of LDM threads.

In NDB 8.0, an initial restart is *not* required to effect a change in this parameter, as it was in some older versions of NDB Cluster.

- `NoOfFragmentLogParts`

Table 22.153 This table provides type and value information for the NoOfFragmentLogParts multi-threaded data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	4
Range	4, 8, 12, 16, 24, 32
Restart Type	IN

Set the number of log file groups for redo logs belonging to this `ndbmtd`. The maximum value is 32; the value set must be an even multiple of 4.

`NoOfFragmentLogParts` should be set equal to the number of LDM threads used by `ndbmtd` as determined by the setting for `MaxNoOfExecutionThreads`. A configuration where this number is any greater than 4 is disallowed.

See the description of `MaxNoOfExecutionThreads` for more information.

- `ThreadConfig`

Table 22.154 This table provides type and value information for the ThreadConfig multi-threaded data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	string
Default	''
Range	...
Restart Type	SI

This parameter is used with `ndbmtd` to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```
ThreadConfig := entry[,entry[,...]]

entry := type={param[,param[,...]]}

type := ldm | main | recv | send | rep | io | tc | watchdog | idxbld

param := count=number
  | cpubind=cpu_list
  | cpuset=cpu_list
  | spintime=number
  | realtime={0|1}
  | nosend={0|1}
  | thread_prio={0..10}
  | cpubind_exclusive=cpu_list
  | cpuset_exclusive=cpu_list
```

The curly braces (`{...}`) surrounding the list of parameters are required, even if there is only one parameter in the list.

A *`param`* (parameter) specifies any or all of the following information:

- The number of threads of the given type (`count`).

- The set of CPUs to which the threads of the given type are to be nonexclusively bound. This is determined by either one of `cpubind` or `cpuset`). `cpubind` causes each thread to be bound (nonexclusively) to a CPU in the set; `cpuset` means that each thread is bound (nonexclusively) to the set of CPUs specified.

  On Solaris, you can instead specify a set of CPUs to which the threads of the given type are to be bound exclusively. `cpubind_exclusive` causes each thread to be bound exclusively to a CPU in the set; `cpuset_exclsuive` means that each thread is bound exclusively to the set of CPUs specified.

  Only one of `cpubind`, `cpuset`, `cpubind_exclusive`, or `cpuset_exclusive` can be provided in a single configuration.

- `spintime` determines the wait time in microseconds the thread spins before going to sleep.

  The default value for `spintime` is the value of the `SchedulerSpinTimer` data node configuration parameter.

  `spintime` does not apply to I/O threads, watchdog, or offline index build threads, and so cannot be set for these thread types.

- `realtime` can be set to 0 or 1. If it is set to 1, the threads run with real-time priority. This also means that `thread_prio` cannot be set.

  The `realtime` parameter is set by default to the value of the `RealtimeScheduler` data node configuration parameter.

  `realtime` cannot be set for offline index build threads.

- By setting `nosend` to 1, you can prevent a `main`, `ldm`, `rep`, or `tc` thread from assisting the send threads. This parameter is 0 by default, and cannot be used with other types of threads.

- `thread_prio` is a thread priority level that can be set from 0 to 10, with 10 representing the greatest priority. The default is 5. The precise effects of this parameter are platform-specific, and are described later in this section.

  The thread priority level cannot be set for offline index build threads.

thread_prio settings and effects by platform. The implementation of `thread_prio` differs between Linux/FreeBSD, Solaris, and Windows. In the following list, we discuss its effects on each of these platforms in turn:

- *Linux and FreeBSD*: We map `thread_prio` to a value to be supplied to the `nice` system call. Since a lower niceness value for a process indicates a higher process priority, increasing `thread_prio` has the effect of lowering the `nice` value.

  Table 22.155 Mapping of thread_prio to nice values on Linux and FreeBSD

`thread_prio` value	`nice` value
0	19
1	16
2	12
3	8
4	4
5	0
6	-4

thread_prio value	nice value
7	-8
8	-12
9	-16
10	-20

Some operating systems may provide for a maximum process niceness level of 20, but this is not supported by all targeted versions; for this reason, we choose 19 as the maximum nice value that can be set.

- *Solaris*: Setting thread_prio on Solaris sets the Solaris FX priority, with mappings as shown in the following table:

Table 22.156 Mapping of thread_prio to FX priority on Solaris

thread_prio value	Solaris FX priority
0	15
1	20
2	25
3	30
4	35
5	40
6	45
7	50
8	55
9	59
10	60

A thread_prio setting of 9 is mapped on Solaris to the special FX priority value 59, which means that the operating system also attempts to force the thread to run alone on its own CPU core.

- *Windows*: We map thread_prio to a Windows thread priority value passed to the Windows API SetThreadPriority() function. This mapping is shown in the following table:

Table 22.157 Mapping of thread_prio to Windows thread priority

thread_prio value	Windows thread priority
0 - 1	THREAD_PRIORITY_LOWEST
2 - 3	THREAD_PRIORITY_BELOW_NORMAL
4 - 5	THREAD_PRIORITY_NORMAL
6 - 7	THREAD_PRIORITY_ABOVE_NORMAL
8 - 10	THREAD_PRIORITY_HIGHEST

The *type* attribute represents an NDB thread type. The thread types supported, and the range of permitted count values for each, are provided in the following list:

- ldm: Local query handler (DBLQH kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes. Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. The value set for ldm must be one of the values 1, 2, 4, 6, 8, 12, 16, 24, or 32.

Changing the number of LDM threads normally requires a system restart to be effective and safe for cluster operations, this requirement is relaxed in certain cases, as explained later in this section. (This is also true when this is done using `MaxNoOfExecutionThreads`.) If `IndexMemory` usage is in excess of 50%, an initial restart of the cluster is required; a maximum of 30-35% `IndexMemory` usage is recommended in such cases. Otherwise, allocation of memory and LDM threads cannot be balanced between nodes, which can ultimately lead to data node failures.

Adding large tablespaces (hundreds of gigabytes or more) for Disk Data tables when using more than the default number of LDMs may cause issues with resource and CPU usage if `DiskPageBufferMemory` is not sufficiently large.

- `tc`: Transaction coordinator thread (`DBTC` kernel block) containing the state of an ongoing transaction. The maximum number of TC threads is 32.

  Optimally, every new transaction can be assigned to a new TC thread. In most cases 1 TC thread per 2 LDM threads is sufficient to guarantee that this can happen. In cases where the number of writes is relatively small when compared to the number of reads, it is possible that only 1 TC thread per 4 LQH threads is required to maintain transaction states. Conversely, in applications that perform a great many updates, it may be necessary for the ratio of TC threads to LDM threads to approach 1 (for example, 3 TC threads to 4 LDM threads).

  Setting `tc` to 0 causes TC handling to be done by the main thread. In most cases, this is effectively the same as setting it to 1.

  Range: 0 - 32

- `main`: Data dictionary and transaction coordinator (`DBDIH` and `DBTC` kernel blocks), providing schema management. This is always handled by a single dedicated thread.

  Range: 1 only.

- `recv`: Receive thread (`CMVMI` kernel block). Each receive thread handles one or more sockets for communicating with other nodes in an NDB Cluster, with one socket per node. NDB Cluster supports multiple receive threads; the maximum is 16 such threads.

  Range: 1 - 16

- `send`: Send thread (`CMVMI` kernel block). To increase throughput, it is possible to perform sends from one or more separate, dedicated threads (maximum 8).

  Previously, all threads handled their own sending directly; this can still be made to happen by setting the number of send threads to 0 (this also happens when `MaxNoOfExecutionThreads` is set less than 10). While doing so can have an adeverse impact on throughput, it can also in some cases provide decreased latency.

  Range: 0 - 16

- `rep`: Replication thread (`SUMA` kernel block). Asynchronous replication operations are always handled by a single, dedicated thread.

  Range: 1 only.

- `io`: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.

  Range: 1 only.

- `watchdog`: Parameters settings associated with this type are actually applied to several threads, each having a specific use. These threads include the `SocketServer` thread, which receives

connection setups from other nodes; the `SocketClient` thread, which attempts to set up connections to other nodes; and the thread watchdog thread that checks that threads are progressing.

Range: 1 only.

- `idxbld`: Offline index build threads. Unlike the other thread types listed previously, which are permanent, these are temporary threads which are created and used only during node or system restarts, or when running `ndb_restore --rebuild-indexes`. They may be bound to CPU sets which overlap with CPU sets bound to permanent thread types.

  `thread_prio`, `realtime`, and `spintime` values cannot be set for offline index build threads. In addition, `count` is ignored for this type of thread.

  If `idxbld` is not specified, the default behavior is as follows:

  - Offline index build threads are not bound if the I/O thread is also not bound, and these threads use any available cores.
  - If the I/O thread is bound, then the offline index build threads are bound to the entire set of bound threads, due to the fact that there should be no other tasks for these threads to perform.

  Range: 0 - 1.

Changing `ThreadCOnfig` normally requires a system initial restart, but this requirement can be relaxed under certain cirumstances:

- If, following the change, the number of LDM threads remains the same as before, nothing more than a simple node restart (rolling restart, or *N*) is required to implement the change.
- Otherwise (that is, if the number of LDM threads changes), it is still possible to effect the change using a node initial restart (*NI*) provided the following two conditions are met:

  a. Each LDM thread handles a maximum of 8 fragments, and

  b. The total number of table fragments is an integer multiple of the number of LDM threads.

In any other case, a system initial restart is needed to change this parameter.

`NDB` can distinguish between thread types by both of the following criteria:

- Whether the thread is an execution thread. Threads of type `main`, `ldm`, `recv`, `rep`, `tc`, and `send` are execution threads; `io`, `watchdog`, and `idxbld` threads are not considered execution threads.
- Whether the allocation of threads to a given task is permanent or temporary. Currently all thread types except `idxbld` are considered permanent; `idxbld` threads are regarded as temporary threads.

Simple examples:

```
# Example 1.

ThreadConfig=ldm={count=2,cpubind=1,2},main={cpubind=12},rep={cpubind=11}

# Example 2.

Threadconfig=main={cpubind=0},ldm={count=4,cpubind=1,2,5,6},io={cpubind=3}
```

It is usually desirable when configuring thread usage for a data node host to reserve one or more number of CPUs for operating system and other tasks. Thus, for a host machine with 24 CPUs, you might want to use 20 CPU threads (leaving 4 for other uses), with 8 LDM threads, 4 TC threads (half the number of LDM threads), 3 send threads, 3 receive threads, and 1 thread each for schema

management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when `MaxNoOfExecutionThreads` is set equal to 20.) The following `ThreadConfig` setting performs these assignments, additionally binding all of these threads to specific CPUs:

```
ThreadConfig=ldm{count=8,cpubind=1,2,3,4,5,6,7,8},main={cpubind=9},io={cpubind=9}, \
rep={cpubind=10},tc{count=4,cpubind=11,12,13,14},recv={count=3,cpubind=15,16,17}, \
send{count=3,cpubind=18,19,20}
```

It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.

The following example incorporates groups of CPUs defined using both `cpuset` and `cpubind`, as well as use of thread prioritization.

```
ThreadConfig=ldm={count=4,cpuset=0-3,thread_prio=8,spintime=200}, \
ldm={count=4,cpubind=4-7,thread_prio=8,spintime=200}, \
tc={count=4,cpuset=8-9,thread_prio=6},send={count=2,thread_prio=10,cpubind=10-11}, \
main={count=1,cpubind=10},rep={count=1,cpubind=11}
```

In this case we create two LDM groups; the first uses `cpubind` and the second uses `cpuset`. `thread_prio` and `spintime` are set to the same values for each group. This means there are eight LDM threads in total. (You should ensure that `NoOfFragmentLogParts` is also set to 8.) The four TC threads use only two CPUs; it is possible when using `cpuset` to specify fewer CPUs than threads in the group. (This is not true for `cpubind`.) The send threads use two threads using `cpubind` to bind these threads to CPUs 10 and 11. The main and rep threads can reuse these CPUs.

This example shows how `ThreadConfig` and `NoOfFragmentLogParts` might be set up for a 24-CPU host with hyperthreading, leaving CPUs 10, 11, 22, and 23 available for operating system functions and interrupts:

```
NoOfFragmentLogParts=10
ThreadConfig=ldm={count=10,cpubind=0-4,12-16,thread_prio=9,spintime=200}, \
tc={count=4,cpuset=6-7,18-19,thread_prio=8},send={count=1,cpuset=8}, \
recv={count=1,cpuset=20},main={count=1,cpuset=9,21},rep={count=1,cpuset=9,21}, \
io={count=1,cpuset=9,21,thread_prio=8},watchdog={count=1,cpuset=9,21,thread_prio=9}
```

The next few examples include settings for `idxbld`. The first two of of these demonstrate how a CPU set defined for `idxbld` can overlap those specified for other (permanent) thread types, the first using `cpuset` and the second using `cpubind`:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8},idxbld={cpuset=1-8}

ThreadConfig=main,ldm={count=1,cpubind=1},idxbld={count=1,cpubind=1}
```

The next example specifies a CPU for the I/O thread, but not for the index build threads:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8}
```

Since the `ThreadConfig` setting just shown locks threads to eight cores numbered 1 through 8, it is equivalent to the setting shown here:

```
ThreadConfig=main,ldm={count=4,cpuset=1-4},tc={count=4,cpuset=5,6,7}, \
io={cpubind=8},idxbld={cpuset=1,2,3,4,5,6,7,8}
```

In order to take advantage of the enhanced stability that the use of `ThreadConfig` offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting `IRQBALANCE_BANNED_CPUS` in `/etc/sysconfig/irqbalance` to `0xFFFFF0`, and by using the

`isolcpus` boot option in `grub.conf`. For specific information, see your operating system or platform documentation.

Disk Data Configuration Parameters. Configuration parameters affecting Disk Data behavior include the following:

- `DiskPageBufferEntries`

Table 22.158 This table provides type and value information for the DiskPageBufferEntries data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	32K pages
Default	10
Range	1 - 1000
Restart Type	N

This is the number of page entries (page references) to allocate. It is specified as a number of 32K pages in `DiskPageBufferMemory`. The default is sufficient for most cases but you may need to increase the value of this parameter if you encounter problems with very large transactions on Disk Data tables. Each page entry requires approximately 100 bytes.

- `DiskPageBufferMemory`

Table 22.159 This table provides type and value information for the DiskPageBufferMemory data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	64M
Range	4M - 1T
Restart Type	N

This determines the amount of space used for caching pages on disk, and is set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` file. It is measured in bytes. Each page takes up 32 KB. This means that NDB Cluster Disk Data storage always uses *`N`* * 32 KB memory where *`N`* is some nonnegative integer.

The default value for this parameter is `64M` (2000 pages of 32 KB each).

If the value for `DiskPageBufferMemory` is set too low in conjunction with using more than the default number of LDM threads in `ThreadConfig` (for example `{ldm=6...}`), problems can arise when trying to add a large (for example 500G) data file to a disk-based `NDB` table, wherein the process takes indefinitely long while occupying one of the CPU cores.

This is due to the fact that, as part of adding a data file to a tablespace, extent pages are locked into memory in an extra PGMAN worker thread, for quick metadata access. When adding a large file, this worker has insufficient memory for all of the data file metadata. In such cases, you should either increase `DiskPageBufferMemory`, or add smaller tablespace files. You may also need to adjust `DiskPageBufferEntries`.

You can query the `ndbinfo.diskpagebuffer` table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See Section 22.5.10.20, “The ndbinfo diskpagebuffer Table”, for more information.

- SharedGlobalMemory

Table 22.160 This table provides type and value information for the SharedGlobalMemory data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	128M
Range	0 - 64T
Restart Type	N

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, UNDO files, and data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the UNDO_BUFFER_SIZE option used with CREATE LOGFILE GROUP and ALTER LOGFILE GROUP statements, including any default value implied for this options by the setting of the InitialLogFileGroup data node configuration parameter. SharedGlobalMemory can be set in the [ndbd] or [ndbd default] section of the config.ini configuration file, and is measured in bytes.

The default value is 128M.

- DiskIOThreadPool

Table 22.161 This table provides type and value information for the DiskIOThreadPool data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	threads
Default	2
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter determines the number of unbound threads used for Disk Data file access. Before DiskIOThreadPool was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With DiskIOThreadPool, you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all of these sets of files, then you can set DiskIOThreadPool higher to enable separate threads to handle the files on each disk.
- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for DiskIOThreadPool.

The default value for this parameter is 2.

- **Disk Data file system parameters.** The parameters in the following list make it possible to place NDB Cluster Disk Data files in specific directories without the need for using symbolic links.

  - `FileSystemPathDD`

    Table 22.162 This table provides type and value information for the FileSystemPathDD data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	filename
Default	[see text]
Range	...
Restart Type	IN

    If this parameter is specified, then NDB Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles`, `FileSystemPathUndoFiles`, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement, and for undo log files by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement. If `FileSystemPathDD` is not specified, then `FileSystemPath` is used.

    If a `FileSystemPathDD` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

  - `FileSystemPathDataFiles`

    Table 22.163 This table provides type and value information for the FileSystemPathDataFiles data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	filename
Default	[see text]
Range	...
Restart Type	IN

    If this parameter is specified, then NDB Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

    If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

  - `FileSystemPathUndoFiles`

Table 22.164 This table provides type and value information for the FileSystemPathUndoFiles data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	filename
Default	[see text]
Range	...
Restart Type	IN

If this parameter is specified, then NDB Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD UNDO` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement used to create that data file. If `FileSystemPathUndoFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathUndoFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see Section 22.5.13.1, “NDB Cluster Disk Data Objects”.

- **Disk Data object creation parameters.** The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

  - `InitialLogFileGroup`

    Table 22.165 This table provides type and value information for the InitialLogFileGroup data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	string
Default	[see text]
Range	...
Restart Type	S

    This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. `InitialLogFileGroup` is specified as shown here:

    ```
    InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list

    file-specification-list:
        file-specification[; file-specification[; ...]]

    file-specification:
        filename:size
    ```

    The `name` of the log file group is optional and defaults to `DEFAULT-LG`. The `undo_buffer_size` is also optional; if omitted, it defaults to `64M`. Each *`file-specification`* corresponds to an undo log file, and at least one must be specified in the *`file-specification-list`*. Undo log files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathUndoFiles`, just as if they had been created as the result of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement.

Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
    ADD UNDOFILE 'undo1.log'
    INITIAL_SIZE 250M
    UNDO_BUFFER_SIZE 128M
    ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
    ADD UNDOFILE 'undo2.log'
    INITIAL_SIZE 150M
    ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

Resources for the initial log file group are added to the global memory pool along with those indicated by the value of `SharedGlobalMemory`.

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini` file. The behavior of an NDB Cluster when different values are set on different data nodes is not defined.

- `InitialTablespace`

Table 22.166 This table provides type and value information for the InitialTablespace data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	string
Default	[see text]
Range	...
Restart Type	S

This parameter can be used to specify an NDB Cluster Disk Data tablespace that is created when performing an initial start of the cluster. `InitialTablespace` is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The `name` of the tablespace is optional and defaults to `DEFAULT-TS`. The `extent_size` is also optional; it defaults to `1M`. The *`file-specification-list`* uses the same syntax as shown with the `InitialLogfileGroup` parameter, the only difference being that each *`file-specification`* used with `InitialTablespace` corresponds to a data file. At least one must be specified in the *`file-specification-list`*. Data files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathDataFiles`, just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying `InitialTablespace` in the `[ndbd default]` section of the `config.ini` file (as with `InitialLogfileGroup`, this parameter should always be set in the `[ndbd default]` section, as the behavior of an NDB Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
    ADD DATAFILE 'data1.dat'
    EXTENT_SIZE 8M
    INITIAL_SIZE 2G
    ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
    ADD DATAFILE 'data2.dat'
    INITIAL_SIZE 4G
    ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating NDB Cluster Disk Data tables thereafter.

Disk Data and GCP Stop errors. Errors encountered when using Disk Data tables such as `Node *nodeid* killed this node because GCP stop was detected` (error 2303) are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of `TimeBetweenGlobalCheckpoints` tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition to the considerations given for `DiskPageBufferMemory` as explained previously, it is also very important that the `DiskIOThreadPool` configuration parameter be set correctly; having `DiskIOThreadPool` set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the `TimeBetweenEpochsTimeout` data node configuration parameter determines the timeout for commits. However, it is possible to disable both types of timeouts by setting this parameter to 0.

Parameters for configuring send buffer memory allocation. Send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The `TotalSendBufferMemory` and `OverLoadLimit` data node configuration parameters permit the setting of limits on this memory allocation. For more information about the use of these parameters (as well as `SendBufferMemory`), see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

- `ExtraSendBufferMemory`

  This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

- `TotalSendBufferMemory`

  This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

  If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

See also Section 22.5.15, “Adding NDB Cluster Data Nodes Online”.

Redo log over-commit handling. It is possible to control a data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by `DefaultOperationRedoProblemAction`. The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- `RedoOverCommitCounter`

Table 22.167 This table provides type and value information for the RedoOverCommitCounter data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	3
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

When `RedoOverCommitLimit` is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for `DefaultOperationRedoProblemAction` (by either queuing the operations to be re-tried, or aborting them).

`RedoOverCommitCounter` defaults to 3. Set it to 0 to disable the limit.

- `RedoOverCommitLimit`

Table 22.168 This table provides type and value information for the RedoOverCommitLimit data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	seconds
Default	20
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than `RedoOverCommitLimit`, is kept and compared with `RedoOverCommitCounter`, and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its `DefaultOperationRedoProblemAction` setting (it either queues the operations to be re-tried, or aborts them).

By default, `RedoOverCommitLimit` is 20 seconds. Set to 0 to disable checking for redo log flush timeouts.

Controlling restart attempts. It is possible to exercise finely-grained control over restart attempts by data nodes when they fail to start using the `MaxStartFailRetries` and `StartFailRetryDelay` data node configuration parameters.

`MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node, `StartFailRetryDelay` sets the number of seconds between retry attempts. These parameters are listed here:

- `StartFailRetryDelay`

  Table 22.169 This table provides type and value information for the StartFailRetryDelay data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

  Use this parameter to set the number of seconds between restart attempts by the data node in the event on failure on startup. The default is 0 (no delay).

  Both this parameter and `MaxStartFailRetries` are ignored unless `StopOnError` is equal to 0.

- `MaxStartFailRetries`

  Table 22.170 This table provides type and value information for the MaxStartFailRetries data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	3
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

  Use this parameter to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

  Both this parameter and `StartFailRetryDelay` are ignored unless `StopOnError` is equal to 0.

NDB index statistics parameters. The parameters in the following list relate to NDB index statistics generation.

- `IndexStatAutoCreate`

  Table 22.171 This table provides type and value information for the IndexStatAutoCreate data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0, 1
Restart Type	S

  Enable (set equal to 1) or disable (set equal to 0) automatic statistics collection when indexes are created. Disabled by default.

- IndexStatAutoUpdate

Table 22.172 This table provides type and value information for the IndexStatAutoUpdate data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0, 1
Restart Type	S

Enable (set equal to 1) or disable (set equal to 0) monitoring of indexes for changes and trigger automatic statistics updates these are detected. The amount and degree of change needed to trigger the updates are determined by the settings for the IndexStatTriggerPct and IndexStatTriggerScale options.

- IndexStatSaveSize

Table 22.173 This table provides type and value information for the IndexStatSaveSize data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	32768
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	IN

Maximum space in bytes allowed for the saved statistics of any given index in the NDB system tables and in the mysqld memory cache. This consumes IndexMemory.

At least one sample is always produced, regardless of any size limit. This size is scaled by IndexStatSaveScale.

The size specified by IndexStatSaveSize is scaled by the value of IndexStatTriggerPct for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting IndexStatTriggerPct equal to 0 disables the scaling effect.

- IndexStatSaveScale

Table 22.174 This table provides type and value information for the IndexStatSaveScale data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	percentage
Default	100
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	IN

The size specified by IndexStatSaveSize is scaled by the value of IndexStatTriggerPct for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting IndexStatTriggerPct equal to 0 disables the scaling effect.

- `IndexStatTriggerPct`

Table 22.175 This table provides type and value information for the IndexStatTriggerPct data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	percentage
Default	100
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	IN

Percentage change in updates that triggers an index statistics update. The value is scaled by `IndexStatTriggerScale`. You can disable this trigger altogether by setting `IndexStatTriggerPct` to 0.

- `IndexStatTriggerScale`

Table 22.176 This table provides type and value information for the IndexStatTriggerScale data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	percentage
Default	100
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	IN

Scale `IndexStatTriggerPct` by this amount times 0.01 for a large index. A value of 0 disables scaling.

- `IndexStatUpdateDelay`

Table 22.177 This table provides type and value information for the IndexStatUpdateDelay data node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	seconds
Default	60
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	IN

Minimum delay in seconds between automatic index statistics updates for a given index. Setting this variable to 0 disables any delay. The default is 60 seconds.

22.3.3.7 Defining SQL and Other API Nodes in an NDB Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes

accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

Note

For a discussion of MySQL server options for NDB Cluster, see MySQL Server Options for NDB Cluster; for information about MySQL server system variables relating to NDB Cluster, see NDB Cluster System Variables.

- `Id`

Table 22.178 This table provides type and value information for the Id API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	[none]
Range	1 - 255
Restart Type	IS

The `Id` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

Note

Data node IDs must be less than 49, regardless of the NDB Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying API nodes. (`Id` continues to be supported for backward compatibility, but is now deprecated and generates a warning when used. It is also subject to future removal.)

- `ConnectionMap`

Table 22.179 This table provides type and value information for the ConnectionMap API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	string
Default	[none]
Range	...
Restart Type	N

Specifies which data nodes to connect.

- `NodeId`

Table 22.180 This table provides type and value information for the NodeId API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13

Property	Value
Type or units	unsigned
Default	[none]
Range	1 - 255
Restart Type	IS

The `NodeId` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

Note

Data node IDs must be less than 49, regardless of the NDB Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes. An alias, `Id`, was used for this purpose in very old versions of NDB Cluster, and continues to be supported for backward compatibility; it is now deprecated and generates a warning when used, and is subject to removal in a future release of NDB Cluster.

- `ExecuteOnComputer`

Table 22.181 This table provides type and value information for the ExecuteOnComputer API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	name
Default	[none]
Range	...
Restart Type	S

This refers to the `Id` set for one of the computers (hosts) defined in a `[computer]` section of the configuration file.

Important

This parameter is deprecated, and is subject to removal in a future release. Use the `HostName` parameter instead.

- `HostName`

Table 22.182 This table provides type and value information for the HostName API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]
Range	...
Restart Type	N

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or `ExecuteOnComputer` is required.

If no `HostName` or `ExecuteOnComputer` is specified in a given `[mysql]` or `[api]` section of the `config.ini` file, then an SQL or API node may connect using the corresponding "slot" from any host which can establish a network connection to the management server host machine. *This differs from the default behavior for data nodes, where `localhost` is assumed for `HostName` unless otherwise specified*.

- `LocationDomainId`

Table 22.183 This table provides type and value information for the LocationDomainId API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 16
Restart Type	S

Assigns an SQL or other API node to a specific availability domain (also known as an availability zone) within a cloud. By informing `NDB` which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use `NDB` transporters' WAN support without any further manual intervention.
- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

`LocationDomainId` takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- `ArbitrationRank`

Table 22.184 This table provides type and value information for the ArbitrationRank API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	0-2
Default	0
Range	0 - 2
Restart Type	N

This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal

configuration uses the management server as arbitrator, setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

By setting `ArbitrationRank` to 0 on all management and SQL nodes, you can disable arbitration completely. You can also control arbitration by overriding this parameter; to do so, set the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file.

- `ArbitrationDelay`

Table 22.185 This table provides type and value information for the ArbitrationDelay API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	milliseconds
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- `BatchByteSize`

Table 22.186 This table provides type and value information for the BatchByteSize API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	16K
Range	1K - 1M
Restart Type	N

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (`BatchSize`) and in terms of bytes (`BatchByteSize`). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

This parameter is measured in bytes. The default value is 16K.

- `BatchSize`

Table 22.187 This table provides type and value information for the BatchSize API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	records
Default	256

Property	Value
Range	1 - 992
Restart Type	N

This parameter is measured in number of records and is by default set to 256. The maximum size is 992.

- `ExtraSendBufferMemory`

Table 22.188 This table provides type and value information for the ExtraSendBufferMemory API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

- `HeartbeatThreadPriority`

Table 22.189 This table provides type and value information for the HeartbeatThreadPriority API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	string
Default	[none]
Range	...
Restart Type	S

Use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes. The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
  {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of `FIFO` (first in, first in) or `RR` (round robin). This followed optionally by the priority (an integer).

- `MaxScanBatchSize`

Table 22.190 This table provides type and value information for the MaxScanBatchSize API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	256K

Property	Value
Range	32K - 16M
Restart Type	N

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- `TotalSendBufferMemory`

Table 22.191 This table provides type and value information for the TotalSendBufferMemory API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	0
Range	256K - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

- `AutoReconnect`

Table 22.192 This table provides type and value information for the AutoReconnect API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

This parameter is `false` by default. This forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an existing one, as re-use of connections can cause problems when using dynamically-allocated node IDs. (Bug #45921)

Note

This parameter can be overridden using the NDB API. For more information, see Ndb_cluster_connection::set_auto_reconnect(), and Ndb_cluster_connection::get_auto_reconnect().

- `DefaultOperationRedoProblemAction`

Table 22.193 This table provides type and value information for the DefaultOperationRedoProblemAction API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	enumeration
Default	QUEUE
Range	ABORT, QUEUE
Restart Type	S

This parameter (along with `RedoOverCommitLimit` and `RedoOverCommitCounter`) controls the data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of `DefaultOperationRedoProblemAction`, listed here:

- `ABORT`: Any pending operations from aborted transactions are also aborted.
- `QUEUE`: Pending operations from transactions that were aborted are queued up to be re-tried. This the default. Pending operations are still aborted when the redo log runs out of space—that is, when **`P_TAIL_PROBLEM`** errors occur.

- `DefaultHashMapSize`

Table 22.194 This table provides type and value information for the DefaultHashMapSize API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	buckets
Default	3840
Range	0 - 3840
Restart Type	N

The size of the table hash maps used by `NDB` is configurable using this parameter. `DefaultHashMapSize` can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table.

Table 22.195 DefaultHashMapSize parameter values

Value	Description / Effect
`0`	Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.
`240`	Old default hash map size
`3840`	Hash map size used by default in NDB 8.0

The original intended use for this parameter was to facilitate upgrades and downgrades to and from older NDB Cluster versions, in which the hash map size differed, due to the fact that this change was not otherwise backward compatible. This is not an issue when upgrading to or downgrading from NDB Cluster 8.0.

- `Wan`

Table 22.196 This table provides type and value information for the wan API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

Use WAN TCP setting as default.

- `ConnectBackoffMaxTime`

Table 22.197 This table provides type and value information for the ConnectBackoffMaxTime API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the `StartConnectBackoffMaxTime` parameter is applied; otherwise, `ConnectBackoffMaxTime` is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches `ConnectBackoffMaxTime` milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up `HeartbeatIntervalDbApi` for the API node to be notified that this has occurred.

- `StartConnectBackoffMaxTime`

Table 22.198 This table provides type and value information for the StartConnectBackoffMaxTime API node configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)

Property	Value
Restart Type	N

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the `StartConnectBackoffMaxTime` parameter is applied; otherwise, `ConnectBackoffMaxTime` is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches `StartConnectBackoffMaxTime` milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up `HeartbeatIntervalDbApi` for the API node to be notified that this has occurred.

API Node Debugging Parameters. You can use the `ApiVerbose` configuration parameter to enable debugging output from a given API node. This parameter takes an integer value. 0 is the default, and disables such debugging; 1 enables debugging output to the cluster log; 2 adds `DBDICT` debugging output as well. (Bug #20638450) See also DUMP 1229.

You can also obtain information from a MySQL server running as an NDB Cluster SQL node using `SHOW STATUS` in the `mysql` client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----------------------------+----------------+
| Variable_name               | Value          |
+-----------------------------+----------------+
| Ndb_cluster_node_id         | 5              |
| Ndb_config_from_host        | 198.51.100.112 |
| Ndb_config_from_port        | 1186           |
| Ndb_number_of_storage_nodes | 4              |
+-----------------------------+----------------+
4 rows in set (0.02 sec)
```

For information about the status variables appearing in the output from this statement, see NDB Cluster Status Variables.

Note

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

22.3.3.8 Defining the System

The `[system]` section is used for parameters applying to the cluster as a whole. The `Name` system parameter is used with MySQL Enterprise Monitor; `ConfigGenerationNumber` and `PrimaryMGMNode` are not used in production environments. Except when using NDB Cluster with MySQL Enterprise Monitor, is not necessary to have a `[system]` section in the `config.ini` file.

More information about these parameters can be found in the following list:

- `ConfigGenerationNumber`

Table 22.199 This table provides type and value information for the ConfigGenerationNumber system configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

Configuration generation number. This parameter is currently unused.

- `Name`

Table 22.200 This table provides type and value information for the Name system configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	string
Default	[none]
Range	...
Restart Type	N

Set a name for the cluster. This parameter is required for deployments with MySQL Enterprise Monitor; it is otherwise unused.

You can obtain the value of this parameter by checking the `Ndb_system_name` status variable. In NDB API applications, you can also retrieve it using `get_system_name()`.

- `PrimaryMGMNode`

Table 22.201 This table provides type and value information for the PrimaryMGMNode system configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

Node ID of the primary management node. This parameter is currently unused.

22.3.3.9 MySQL Server Options and Variables for NDB Cluster

This section provides information about MySQL server options, server and status variables that are specific to NDB Cluster. For general information on using these, and for other options and variables not specific to NDB Cluster, see Section 5.1, “The MySQL Server”.

For NDB Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see Section 22.3, “Configuration of NDB Cluster”.

MySQL Server Options for NDB Cluster

This section provides descriptions of `mysqld` server options relating to NDB Cluster. For information about `mysqld` options not specific to NDB Cluster, and for general information about the use of options with `mysqld`, see Section 5.1.7, “Server Command Options”.

For information about command-line options used with other NDB Cluster processes (`ndbd`, `ndb_mgmd`, and `ndb_mgm`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”. For information about command-line options used with `NDB` utility programs (such as `ndb_desc`, `ndb_size.pl`, and `ndb_show_tables`), see Section 22.4, “NDB Cluster Programs”.

- `--ndbcluster`

Table 22.202 Type and value information for ndbcluster

Property	Value
Name	`ndbcluster`
Command Line	Yes
System Variable	No
Status Variable	No
Option File	Yes
Scope	
Dynamic	No
Type	
Default, Range	FALSE (Version: 8.0)
Notes	DESCRIPTION: Enable NDB Cluster (if this version of MySQL supports it) Disabled by `--skip-ndbcluster`.

The `NDBCLUSTER` storage engine is necessary for using NDB Cluster. If a `mysqld` binary includes support for the `NDBCLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

The `--ndbcluster` option is ignored (and the `NDB` storage engine is *not* enabled) if `--initialize` is also used. (It is neither necessary nor desirable to use this option together with `--initialize`.)

- `--ndb-allow-copying-alter-table=[ON|OFF]`

Table 22.203 Type and value information for ndb-allow-copying-alter-table

Property	Value
Name	`ndb-allow-copying-alter-table`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Both
Dynamic	Yes

Property	Value
Type	
Default, Range	ON (Version: 8.0)
Notes	DESCRIPTION: Set to OFF to keep ALTER TABLE from using copying operations on NDB tables

Let `ALTER TABLE` and other DDL statements use copying operations on `NDB` tables. Set to `OFF` to keep this from happening; doing so may improve performance of critical applications.

- `--ndb-batch-size=#`

Table 22.204 Type and value information for ndb-batch-size

Property	Value
Name	`ndb-batch-size`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	No
Type	
Default, Range	32768 / 0 - 31536000 (Version: 8.0)
Notes	DESCRIPTION: Size (in bytes) to use for NDB transaction batches

This sets the size in bytes that is used for NDB transaction batches.

- `--ndb-cluster-connection-pool=#`

Table 22.205 Type and value information for ndb-cluster-connection-pool

Property	Value
Name	`ndb-cluster-connection-pool`
Command Line	Yes
System Variable	Yes
Status Variable	Yes
Option File	Yes
Scope	Global
Dynamic	No
Type	
Default, Range	1 / 1 - 63 (Version: 8.0)
Notes	DESCRIPTION: Number of connections to the cluster used by MySQL

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own `[api]` or `[mysqld]` section in the cluster configuration (`config.ini`) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

Important

Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must *not* use a node ID as part of the cluster connection string when starting any `mysqld` process that employs connection pooling.

Setting a node ID in the connection string when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

- `--ndb-cluster-connection-pool-nodeids=`*`list`*

Table 22.206 Type and value information for ndb-cluster-connection-pool-nodeids

Property	Value
Name	`ndb-cluster-connection-pool-nodeids`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	No
Type	
Default, Range	/ (Version: 8.0)
Notes	DESCRIPTION: Comma-separated list of node IDs for connections to the cluster used by MySQL; the number of nodes in the list must be the same as the value set for --ndb-cluster-connection-pool

Specifies a comma-separated list of node IDs for connections to the cluster used by an SQL node. The number of nodes in this list must be the same as the value set for the `--ndb-cluster-connection-pool` option.

- `--ndb-blob-read-batch-bytes=`*`bytes`*

Table 22.207 Type and value information for ndb-blob-read-batch-bytes

Property	Value
Name	`ndb-blob-read-batch-bytes`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes

Property	Value
Scope	Both
Dynamic	Yes
Type	
Default, Range	65536 / 0 - 4294967295 (Version: NDB 8.0)
Notes	DESCRIPTION: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.

This option can be used to set the size (in bytes) for batching of `BLOB` data reads in NDB Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be read within the current transaction, any pending `BLOB` read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling `BLOB` read batching.

Note

In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobReadBytes()` and `getMaxPendingBlobReadBytes()` methods.

- `--ndb-blob-write-batch-bytes=`*`bytes`*

Table 22.208 Type and value information for ndb-blob-write-batch-bytes

Property	Value
Name	`ndb-blob-write-batch-bytes`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Both
Dynamic	Yes
Type	
Default, Range	65536 / 0 - 4294967295 (Version: 8.0)
Notes	DESCRIPTION: Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.

This option can be used to set the size (in bytes) for batching of `BLOB` data writes in NDB Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be written within the current transaction, any pending `BLOB` write operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling `BLOB` write batching.

Note

In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobWriteBytes()` and `getMaxPendingBlobWriteBytes()` methods.

- `--ndb-connectstring=`*`connection_string`*

Table 22.209 Type and value information for ndb-connectstring

Property	Value
Name	`ndb-connectstring`
Command Line	Yes
System Variable	No
Status Variable	No
Option File	Yes
Scope	
Dynamic	No
Type	
Default, Range	(Version: 8.0)
Notes	DESCRIPTION: Point to the management server that distributes the cluster configuration

When using the `NDBCLUSTER` storage engine, this option specifies the management server that distributes cluster configuration data. See Section 22.3.3.3, “NDB Cluster Connection Strings”, for syntax.

- `--ndb-default-column-format=[FIXED|DYNAMIC]`

Table 22.210 Type and value information for ndb-default-column-format

Property	Value
Name	`ndb-default-column-format`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	DYNAMIC / FIXED, DYNAMIC (Version: NDB 8.0)
Default, Range	FIXED / FIXED, DYNAMIC (Version: NDB 8.0)
Notes	DESCRIPTION: Use this value (FIXED or DYNAMIC) by default for COLUMN_FORMAT and ROW_FORMAT options when creating or adding columns to a table.

Sets the default `COLUMN_FORMAT` and `ROW_FORMAT` for new tables (see Section 13.1.20, “CREATE TABLE Syntax”). The default is `FIXED`.

- `--ndb-deferred-constraints=[0|1]`

Table 22.211 Type and value information for ndb-deferred-constraints

Property	Value
Name	`ndb-deferred-constraints`
Command Line	Yes
System Variable	Yes

Property	Value
Status Variable	No
Option File	Yes
Scope	Both
Dynamic	Yes
Type	
Default, Range	0 / 0 - 1 (Version: 8.0)
Notes	DESCRIPTION: Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.

Controls whether or not constraint checks on unique indexes are deferred until commit time, where such checks are supported. `0` is the default.

This option is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- `--ndb-distribution=[KEYHASH|LINHASH]`

Table 22.212 Type and value information for ndb-distribution

Property	Value
Name	`ndb-distribution`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	KEYHASH / LINHASH, KEYHASH (Version: 8.0)
Notes	DESCRIPTION: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)

Controls the default distribution method for `NDB` tables. Can be set to either of `KEYHASH` (key hashing) or `LINHASH` (linear hashing). `KEYHASH` is the default.

- `--ndb-log-apply-status`

Table 22.213 Type and value information for ndb-log-apply-status

Property	Value
Name	`ndb-log-apply-status`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	No

Property	Value
Type	
Default, Range	OFF (Version: 8.0)
Notes	DESCRIPTION: Cause a MySQL server acting as a slave to log mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID. Effective only if the server is started with the --ndbcluster option.

Causes a slave `mysqld` to log any updates received from its immediate master to the `mysql.ndb_apply_status` table in its own binary log using its own server ID rather than the server ID of the master. In a circular or chain replication setting, this allows such updates to propagate to the `mysql.ndb_apply_status` tables of any MySQL servers configured as slaves of the current `mysqld`.

In a chain replication setup, using this option allows downstream (slave) clusters to be aware of their positions relative to all of their upstream contributors (masters).

In a circular replication setup, this option causes changes to `ndb_apply_status` tables to complete the entire circuit, eventually propagating back to the originating NDB Cluster. This also allows a cluster acting as a master to see when its changes (epochs) have been applied to the other clusters in the circle.

This option has no effect unless the MySQL server is started with the `--ndbcluster` option.

- `--ndb-log-empty-epochs=[ON|OFF]`

Table 22.214 Type and value information for ndb-log-empty-epochs

Property	Value
Name	`ndb-log-empty-epochs`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	OFF (Version: 8.0)
Notes	DESCRIPTION: When enabled, causes epochs in which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.

Causes epochs during which there were no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `--log-slave-updates` is enabled.

By default this option is disabled. Disabling `--ndb-log-empty-epochs` causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

Because `--ndb-log-empty-epochs=1` causes the size of the `ndb_binlog_index` table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

- `--ndb-log-empty-update=[ON|OFF]`

Table 22.215 Type and value information for ndb-log-empty-update

Property	Value
Name	ndb-log-empty-update
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	OFF (Version: 8.0)
Notes	DESCRIPTION: When enabled, causes updates that produced no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.

Causes updates that produced no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `--log-slave-updates` is enabled.

By default this option is disabled (`OFF`). Disabling `--ndb-log-empty-update` causes updates with no changes not to be written to the binary log.

- `--ndb-log-exclusive-reads=[0|1]`

Table 22.216 Type and value information for ndb-log-exclusive-reads

Property	Value
Name	ndb-log-exclusive-reads
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Both
Dynamic	Yes
Type	
Default, Range	0 (Version: 8.0)
Notes	DESCRIPTION: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts

Starting the server with this option causes primary key reads to be logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. You can also enable and disable these locks at runtime by setting the value of the `ndb_log_exclusive_reads` system variable to 1 or 0, respectively. 0 (disable locking) is the default.

For more information, see Read conflict detection and resolution.

- `--ndb-log-orig`

Table 22.217 Type and value information for ndb-log-orig

Property	Value
Name	`ndb-log-orig`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	No
Type	
Default, Range	OFF (Version: 8.0)
Notes	DESCRIPTION: Log originating server id and epoch in mysql.ndb_binlog_index table

Log the originating server ID and epoch in the `ndb_binlog_index` table.

Note

This makes it possible for a given epoch to have multiple rows in `ndb_binlog_index`, one for each originating epoch.

For more information, see Section 22.6.4, “NDB Cluster Replication Schema and Tables”.

- `--ndb-log-transaction-id`

Table 22.218 Type and value information for ndb-log-transaction-id

Property	Value
Name	`ndb-log-transaction-id`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	No
Type	
Default, Range	OFF (Version: 8.0)
Notes	DESCRIPTION: Write NDB transaction IDs in the binary log. Requires --log-bin-v1-events=OFF.

Causes a slave `mysqld` to write the NDB transaction ID in each row of the binary log. Such logging requires the use of the Version 2 event format for the binary log; thus, `--log-bin-use-v1-row-events` must be set to `FALSE` in order to use this option.

This option is not supported in mainline MySQL Server 8.0. It is required to enable NDB Cluster Replication conflict detection and resolution using the `NDB$EPOCH_TRANS()` function (see NDB $EPOCH_TRANS()).

The default value is `FALSE`.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `--ndb-log-update-minimal`

Table 22.219 Type and value information for ndb-log-update-minimal

Property	Value
Name	`ndb-log-update-minimal`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	OFF (Version: NDB 8.0)
Default, Range	OFF (Version: NDB 8.0)
Default, Range	OFF (Version: NDB 8.0)
Notes	DESCRIPTION: Log updates in a minimal format.

Log updates in a minimal fashion, by writing only the primary key values in the before image, and only the changed columns in the after image. This may cause compatibility problems if replicating to storage engines other than `NDB`.

- `--ndb-mgmd-host=host[:port]`

Table 22.220 Type and value information for ndb-mgmd-host

Property	Value
Name	`ndb-mgmd-host`
Command Line	Yes
System Variable	No
Status Variable	No
Option File	Yes
Scope	
Dynamic	No
Type	
Default, Range	localhost:1186 (Version: 8.0)
Notes	DESCRIPTION: Set the host (and port, if desired) for connecting to management server

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=#`

Table 22.221 Type and value information for ndb-nodeid

Property	Value
Name	`ndb-nodeid`
Command Line	Yes
System Variable	No
Status Variable	Yes
Option File	Yes
Scope	Global
Dynamic	No
Type	
Default, Range	/ 1 - 63 (Version: NDB 8.0)
Default, Range	/ 1 - 255 (Version: NDB 8.0)
Notes	DESCRIPTION: NDB Cluster node ID for this MySQL server

Set this MySQL server's node ID in an NDB Cluster.

The `--ndb-nodeid` option overrides any node ID set with `--ndb-connectstring`, regardless of the order in which the two options are used.

In addition, if `--ndb-nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an "open" `[mysqld]` or `[api]` section in the file (that is, a section without a `NodeId` or `Id` parameter specified). This is also true if the node ID is specified as part of the connection string.

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection` row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for NDB Cluster SQL nodes, see Section 22.3.3.7, "Defining SQL and Other API Nodes in an NDB Cluster".

- `--ndb_optimization_delay=`*`milliseconds`*

Table 22.222 Type and value information for ndb_optimization_delay

Property	Value
Name	`ndb_optimization_delay`
Command Line	No
System Variable	Yes
Status Variable	No
Option File	No
Scope	Global
Dynamic	Yes
Type	
Default, Range	10 / 0 - 100000 (Version: 8.0)
Notes	DESCRIPTION: Sets the number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables

Set the number of milliseconds to wait between sets of rows by `OPTIMIZE TABLE` statements on `NDB` tables. The default is 10.

- `--ndb-recv-thread-activation-threshold=threshold`

Table 22.223 Type and value information for ndb-recv-thread-activation-threshold

Property	Value
Name	ndb-recv-thread-activation-threshold
Command Line	Yes
System Variable	No
Status Variable	No
Option File	Yes
Scope	
Dynamic	No
Type	
Default, Range	8 / 0 (MIN_ACTIVATION_THRESHOLD) - 16 (MAX_ACTIVATION_THRESHOLD) (Version: NDB 8.0)
Notes	DESCRIPTION: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads)

When this number of concurrently active threads is reached, the receive thread takes over polling of the cluster connection.

- `--ndb-recv-thread-cpu-mask=bitmask`

Table 22.224 Type and value information for ndb-recv-thread-cpu-mask

Property	Value
Name	ndb-recv-thread-cpu-mask
Command Line	Yes
System Variable	No
Status Variable	No
Option File	Yes
Scope	
Dynamic	No
Type	
Default, Range	[empty] (Version: 8.0)
Notes	DESCRIPTION: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.

Set a CPU mask for locking receiver threads to specific CPUs. This is specified as a hexadecimal bitmask; for example, `0x33` means that one CPU is used per receiver thread. An empty string (no locking of receiver threads) is the default.

- `ndb-transid-mysql-connection-map=state`

Table 22.225 Type and value information for ndb-transid-mysql-connection-map

Property	Value
Name	ndb-transid-mysql-connection-map
Command Line	Yes
System Variable	No
Status Variable	No
Option File	No
Scope	
Dynamic	No
Type	
Default, Range	ON / ON, OFF, FORCE (Version: 8.0)
Notes	DESCRIPTION: Enable or disable the ndb_transid_mysql_connection_map plugin; that is, enable or disable the INFORMATION_SCHEMA table having that name

Enables or disables the plugin that handles the `ndb_transid_mysql_connection_map` table in the `INFORMATION_SCHEMA` database. Takes one of the values `ON`, `OFF`, or `FORCE`. `ON` (the default) enables the plugin. `OFF` disables the plugin, which makes `ndb_transid_mysql_connection_map` inaccessible. `FORCE` keeps the MySQL Server from starting if the plugin fails to load and start.

You can see whether the `ndb_transid_mysql_connection_map` table plugin is running by checking the output of `SHOW PLUGINS`.

- `--ndb-wait-connected=`*`seconds`*

Table 22.226 Type and value information for ndb-wait-connected

Property	Value
Name	ndb-wait-connected
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	No
Type	
Default, Range	0 / 0 - 31536000 (Version: 8.0)
Default, Range	30 / 0 - 31536000 (Version: NDB 8.0)
Default, Range	0 / 0 - 31536000 (Version: 8.0)
Default, Range	30 / 0 - 31536000 (Version: NDB 8.0)
Notes	DESCRIPTION: Time (in seconds) for the MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections

This option sets the period of time that the MySQL server waits for connections to NDB Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds. The default value is `30`.

- `--ndb-wait-setup=seconds`

Table 22.227 Type and value information for ndb-wait-setup

Property	Value
Name	ndb-wait-setup
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	No
Type	
Default, Range	15 / 0 - 31536000 (Version: NDB 8.0)
Default, Range	15 / 0 - 31536000 (Version: NDB 8.0)
Default, Range	15 / 0 - 31536000 (Version: NDB 8.0)
Default, Range	30 / 0 - 31536000 (Version: NDB 8.0)
Default, Range	15 / 0 - 31536000 (Version: NDB 8.0)
Default, Range	30 / 0 - 31536000 (Version: NDB 8.0)
Notes	DESCRIPTION: Time (in seconds) for the MySQL server to wait for NDB engine setup to complete

This variable shows the period of time that the MySQL server waits for the `NDB` storage engine to complete setup before timing out and treating `NDB` as unavailable. The time is specified in seconds. The default value is `30`.

- `--server-id-bits=#`

Table 22.228 Type and value information for server-id-bits

Property	Value
Name	server-id-bits
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	No
Type	
Default, Range	32 / 7 - 32 (Version: 8.0)
Notes	DESCRIPTION: Sets the number of least significant bits in the server_id actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. server_id must be less than 2 to the power of this value.

This option indicates the number of least significant bits within the 32-bit `server_id` which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the `AnyValue` of an `OperationOptions` structure (NDB Cluster uses the `AnyValue` to store the server ID).

When extracting the effective server ID from `server_id` for purposes such as detection of replication loops, the server ignores the remaining bits. The `--server-id-bits` option is used to mask out any irrelevant bits of `server_id` in the IO and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by `mysqlbinlog`, provided that it is run with its own `--server-id-bits` option set to 32 (the default).

The value of `server_id` must be less than 2 ^ `server_id_bits`; otherwise, `mysqld` refuses to start.

This system variable is supported only by NDB Cluster. It is not supported in the standard MySQL 8.0 Server.

- `--skip-ndbcluster`

Table 22.229 Type and value information for skip-ndbcluster

Property	Value
Name	`skip-ndbcluster`
Command Line	Yes
System Variable	No
Status Variable	No
Option File	Yes
Scope	
Dynamic	No
Type	
Notes	DESCRIPTION: Disable the NDB Cluster storage engine

Disable the `NDBCLUSTER` storage engine. This is the default for binaries that were built with `NDBCLUSTER` storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` option is given explicitly. See Section 22.3.1, “Quick Test Setup of NDB Cluster”, for an example.

NDB Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to NDB Cluster and the `NDB` storage engine. For system variables not specific to NDB Cluster, see Section 5.1.8, “Server System Variables”. For general information on using system variables, see Section 5.1.9, “Using System Variables”.

- `ndb_autoincrement_prefetch_sz`

Table 22.230 Type and value information for ndb_autoincrement_prefetch_sz

Property	Value
Name	`ndb_autoincrement_prefetch_sz`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Both
Dynamic	Yes

Property	Value
Type	
Default, Range	32 / 1 - 256 (Version: 8.0)
Default, Range	1 / 1 - 256 (Version: NDB 8.0)
Default, Range	32 / 1 - 256 (Version: NDB 8.0)
Default, Range	1 / 1 - 256 (Version: NDB 8.0)
Default, Range	32 / 1 - 256 (Version: NDB 8.0)
Default, Range	1 / 1 - 256 (Version: NDB 8.0)
Default, Range	32 / 1 - 256 (Version: NDB 8.0)
Default, Range	1 / 1 - 256 (Version: NDB 8.0)
Default, Range	1 / 1 - 65536 (Version: NDB 8.0)
Default, Range	32 / 1 - 256 (Version: NDB 8.0)
Default, Range	1 / 1 - 65536 (Version: NDB 8.0)
Default, Range	1 / 1 - 65536 (Version: NDB 8.0)
Notes	DESCRIPTION: NDB auto-increment prefetch size

Determines the probability of gaps in an autoincremented column. Set it to `1` to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood that consecutive autoincrement numbers will be used in a batch of inserts. The mininum and default value is 1. The maximum value for `ndb_autoincrement_prefetch_sz` is 65536.

This variable affects only the number of `AUTO_INCREMENT` IDs that are fetched between statements; within a given statement, at least 32 IDs are obtained at a time. The default value is 1.

Important

This variable does not affect inserts performed using `INSERT ... SELECT`.

- `ndb_cache_check_time`

Table 22.231 Type and value information for ndb_cache_check_time

Property	Value
Name	`ndb_cache_check_time`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	0 / - (Version: 8.0)
Notes	DESCRIPTION: Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache

The number of milliseconds that elapse between checks of NDB Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

Note

The query cache `ndb_cache_check_time` are deprecated in MySQL 5.7; the query cache was removed in MySQL 8.0.

- `ndb_clear_apply_status`

Table 22.232 Type and value information for ndb_clear_apply_status

Property	Value
Name	`ndb_clear_apply_status`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	No
Scope	Global
Dynamic	Yes
Type	
Default, Range	ON (Version: 8.0)
Notes	DESCRIPTION: Causes RESET SLAVE to clear all rows from the ndb_apply_status table; ON by default

By the default, executing `RESET SLAVE` causes an NDB Cluster replication slave to purge all rows from its `ndb_apply_status` table. You can disable this by setting `ndb_clear_apply_status=OFF`.

- `ndb_data_node_neighbour`

Table 22.233 Type and value information for ndb_data_node_neighbour

Property	Value
Name	`ndb_data_node_neighbour`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	0 / 0 - 255 (Version: NDB 8.0)
Notes	DESCRIPTION: Specifies cluster data node "closest" to this MySQL Server, for transaction hinting and fully replicated tables

Sets the ID of a “nearest” data node—that is, a preferred nonlocal data node is chosen to execute the transaction, rather than one running on the same host as the SQL or API node. This used to ensure that when a fully replicated table is accessed, we access it on this data node, to ensure that

the local copy of the table is always used whenever possible. This can also be used for providing hints for transactions.

This can improve data access times in the case of a node that is physically closer than and thus has higher network throughput than others on the same host.

See Section 13.1.20.11, “Setting NDB_TABLE Options”, for further information.

Note

An equivalent method `set_data_node_neighbour()` is provided for use in NDB API applications.

- `ndb_default_column_format`

Table 22.234 Type and value information for ndb_default_column_format

Property	Value
Name	`ndb_default_column_format`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	DYNAMIC / FIXED, DYNAMIC (Version: NDB 8.0)
Default, Range	FIXED / FIXED, DYNAMIC (Version: NDB 8.0)
Notes	DESCRIPTION: Sets default row format and column format (FIXED or DYNAMIC) used for new NDB tables

Sets the default `COLUMN_FORMAT` and `ROW_FORMAT` for new tables (see Section 13.1.20, “CREATE TABLE Syntax”). The default is `FIXED`.

- `ndb_deferred_constraints`

Table 22.235 Type and value information for ndb_deferred_constraints

Property	Value
Name	`ndb_deferred_constraints`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Both
Dynamic	Yes
Type	
Default, Range	0 / 0 - 1 (Version: 8.0)
Notes	DESCRIPTION: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.

Controls whether or not constraint checks are deferred, where these are supported. `0` is the default.

This variable is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- `ndb_distribution`

Table 22.236 Type and value information for ndb_distribution

Property	Value
Name	`ndb_distribution`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	KEYHASH / LINHASH, KEYHASH (Version: 8.0)
Notes	DESCRIPTION: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)

Controls the default distribution method for `NDB` tables. Can be set to either of `KEYHASH` (key hashing) or `LINHASH` (linear hashing). `KEYHASH` is the default.

- `ndb_eventbuffer_free_percent`

Table 22.237 Type and value information for ndb_eventbuffer_free_percent

Property	Value
Name	`ndb_eventbuffer_free_percent`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	20 / 1 - 99 (Version: 8.0)
Notes	DESCRIPTION: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by ndb_eventbuffer_max_alloc

Sets the percentage of the maximum memory allocated to the event buffer (ndb_eventbuffer_max_alloc) that should be available in event buffer after reaching the maximum, before starting to buffer again.

- `ndb_eventbuffer_max_alloc`

Table 22.238 Type and value information for ndb_eventbuffer_max_alloc

Property	Value
Name	ndb_eventbuffer_max_alloc
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	0 / 0 - 4294967295 (Version: 8.0)
Notes	DESCRIPTION: Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit).

Sets the maximum amount memory (in bytes) that can be allocated for buffering events by the NDB API. 0 means that no limit is imposed, and is the default.

- ndb_extra_logging

Table 22.239 Type and value information for ndb_extra_logging

Property	Value
Name	ndb_extra_logging
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	0 / - (Version: 8.0)
Default, Range	1 / - (Version: NDB 8.0)
Notes	DESCRIPTION: Controls logging of NDB Cluster schema, connection, and data distribution events in the MySQL error log

This variable enables recording in the MySQL error log of information specific to the NDB storage engine.

When this variable is set to 0, the only information specific to NDB that is written to the MySQL error log relates to transaction handling. If it set to a value greater than 0 but less than 10, NDB table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other NDB errors and information. If the value is set to 10 or more, information about NDB internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log. The default is 1.

- ndb_force_send

Table 22.240 Type and value information for ndb_force_send

Property	Value
Name	ndb_force_send
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Both
Dynamic	Yes
Type	
Default, Range	TRUE (Version: 8.0)
Notes	DESCRIPTION: Forces sending of buffers to NDB immediately, without waiting for other threads

Forces sending of buffers to NDB immediately, without waiting for other threads. Defaults to ON.

- ndb_fully_replicated

Table 22.241 Type and value information for ndb_fully_replicated

Property	Value
Name	ndb_fully_replicated
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Both
Dynamic	Yes
Type	
Default, Range	OFF (Version: NDB 8.0)
Notes	DESCRIPTION: Whether new NDB tables are fully replicated

Determines whether new NDB tables are fully replicated. This setting can be overridden for an individual table using COMMENT="NDB_TABLE=FULLY_REPLICATED=..." in a CREATE TABLE or ALTER TABLE statement; see Section 13.1.20.11, “Setting NDB_TABLE Options”, for syntax and other information.

- ndb_index_stat_enable

Table 22.242 Type and value information for ndb_index_stat_enable

Property	Value
Name	ndb_index_stat_enable
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Both

Property	Value
Dynamic	Yes
Type	
Default, Range	OFF (Version: 8.0)
Default, Range	ON (Version: NDB 8.0)
Notes	DESCRIPTION: Use NDB index statistics in query optimization

Use `NDB` index statistics in query optimization. The default is `ON`.

- `ndb_index_stat_option`

Table 22.243 Type and value information for ndb_index_stat_option

Property	Value
Name	`ndb_index_stat_option`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Both
Dynamic	Yes
Type	
Default, Range	loop_enable=1000ms,loop_idle=1000ms,loop_busy=100ms, update_batch=1,read_batch=4,idle_batch=32,check_batch=8, check_delay=10m,delete_batch=8, clean_delay=1m,error_batch=4, error_delay=1m,evict_batch=8,evict_delay=1m,cache_limit=32M, cache_lowpct=90,zero_total=0 (Version: 8.0)
Default, Range	loop_checkon=1000ms,loop_idle=1000ms,loop_busy=100ms, update_batch=1,read_batch=4,idle_batch=32,check_batch=32, check_delay=1m,delete_batch=8,clean_delay=0,error_batch=4, error_delay=1m,evict_batch=8,evict_delay=1m,cache_limit=32M, cache_lowpct=90 (Version: NDB 8.0)
Notes	DESCRIPTION: Comma-separated list of tunable options for NDB index statistics; the list should contain no spaces

This variable is used for providing tuning options for NDB index statistics generation. The list consist of comma-separated name-value pairs of option names and values, and this list must not contain any space characters.

Options not used when setting `ndb_index_stat_option` are not changed from their default values. For example, you can set `ndb_index_stat_option = 'loop_idle=1000ms,cache_limit=32M'`.

Time values can be optionally suffixed with `h` (hours), `m` (minutes), or `s` (seconds). Millisecond values can optionally be specified using `ms`; millisecond values cannot be specified using `h`, `m`, or `s`.) Integer values can be suffixed with `K`, `M`, or `G`.

The names of the options that can be set using this variable are shown in the table that follows. The table also provides brief descriptions of the options, their default values, and (where applicable) their minimum and maximum values.

Table 22.244 ndb_index_stat_option options and values

Name	Description	Default/Units	Minimum/Maximum
loop_enable		1000 ms	0/4G
loop_idle	Time to sleep when idle	1000 ms	0/4G
loop_busy	Time to sleep when more work is waiting	100 ms	0/4G
update_batch		1	0/4G
read_batch		4	1/4G
idle_batch		32	1/4G
check_batch		8	1/4G
check_delay	How often to check for new statistics	10 m	1/4G
delete_batch		8	0/4G
clean_delay		1 m	0/4G
error_batch		4	1/4G
error_delay		1 m	1/4G
evict_batch		8	1/4G
evict_delay	Clean LRU cache, from read time	1 m	0/4G
cache_limit	Maximum amount of memory in bytes used for cached index statistics by this mysqld; clean up the cache when this is exceeded.	32 M	0/4G
cache_lowpct		90	0/100
zero_total	Setting this to 1 resets all accumulating counters in ndb_index_stat_status to 0. This option value is also reset to 0 when this is done.	0	0/1

- ndb_join_pushdown

Table 22.245 Type and value information for ndb_join_pushdown

Property	Value
Name	ndb_join_pushdown
Command Line	No
System Variable	Yes
Status Variable	No
Option File	No
Scope	Both
Dynamic	Yes

Property	Value
Type	
Default, Range	TRUE (Version: NDB 8.0)
Notes	DESCRIPTION: Enables pushing down of joins to data nodes

This variable controls whether joins on `NDB` tables are pushed down to the NDB kernel (data nodes). Previously, a join was handled using multiple accesses of `NDB` by the SQL node; however, when `ndb_join_pushdown` is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to `mysqld`. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, `ndb_join_pushdown` is enabled.

Conditions for NDB pushdown joins. In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use *exactly* the same data type.

   This means that expressions such as `t1.a = t2.a + constant` cannot be pushed down, and that (for example) a join on an `INT` column and a `BIGINT` column also cannot be pushed down.

2. Queries referencing `BLOB` or `TEXT` columns are not supported.

3. Explicit locking is not supported; however, the `NDB` storage engine's characteristic implicit row-based locking is enforced.

   This means that a join using `FOR UPDATE` cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the `ref`, `eq_ref`, or `const` access methods, or some combination of these methods.

   Outer joined child tables can only be pushed using `eq_ref`.

   If the root of the pushed join is an `eq_ref` or `const`, only child tables joined by `eq_ref` can be appended. (A table joined by `ref` is likely to become the root of another pushed join.)

   If the query optimizer decides on `Using join cache` for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by `[LINEAR] HASH`, `LIST`, or `RANGE` currently cannot be pushed down.

You can see whether a given join can be pushed down by checking it with `EXPLAIN`; when the join can be pushed down, you can see references to the `pushed join` in the `Extra` column of the output, as shown in this example:

```
mysql> EXPLAIN
    ->     SELECT e.first_name, e.last_name, t.title, d.dept_name
    ->         FROM employees e
    ->         JOIN dept_emp de ON e.emp_no=de.emp_no
    ->         JOIN departments d ON d.dept_no=de.dept_no
    ->         JOIN titles t ON e.emp_no=t.emp_no\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: d
         type: ALL
possible_keys: PRIMARY
          key: NULL
```

```
      key_len: NULL
          ref: NULL
         rows: 9
        Extra: Parent of 4 pushed join@1
*************************** 2. row ***************************
           id: 1
  select_type: SIMPLE
        table: de
         type: ref
possible_keys: PRIMARY,emp_no,dept_no
          key: dept_no
      key_len: 4
          ref: employees.d.dept_no
         rows: 5305
        Extra: Child of 'd' in pushed join@1
*************************** 3. row ***************************
           id: 1
  select_type: SIMPLE
        table: e
         type: eq_ref
possible_keys: PRIMARY
          key: PRIMARY
      key_len: 4
          ref: employees.de.emp_no
         rows: 1
        Extra: Child of 'de' in pushed join@1
*************************** 4. row ***************************
           id: 1
  select_type: SIMPLE
        table: t
         type: ref
possible_keys: PRIMARY,emp_no
          key: emp_no
      key_len: 4
          ref: employees.de.emp_no
         rows: 19
        Extra: Child of 'e' in pushed join@1
4 rows in set (0.00 sec)
```

Note

If inner joined child tables are joined by `ref`, *and* the result is ordered or grouped by a sorted index, this index cannot provide sorted rows, which forces writing to a sorted tempfile.

Two additional sources of information about pushed join performance are available:

1. The status variables `Ndb_pushed_queries_defined`, `Ndb_pushed_queries_dropped`, `Ndb_pushed_queries_executed`, and `Ndb_pushed_reads`.

2. The counters in the `ndbinfo.counters` table that belong to the `DBSPJ` kernel block. See Section 22.5.10.10, “The ndbinfo counters Table”, for information about these counters. See also The DBSPJ Block, in the *NDB Cluster API Developer Guide*.

- `ndb_log_apply_status`

Table 22.246 Type and value information for ndb_log_apply_status

Property	Value
Name	`ndb_log_apply_status`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes

Property	Value
Scope	Global
Dynamic	No
Type	
Default, Range	OFF (Version: 8.0)
Notes	DESCRIPTION: Whether or not a MySQL server acting as a slave logs mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID

A read-only variable which shows whether the server was started with the `--ndb-log-apply-status` option.

- `ndb_log_bin`

Table 22.247 Type and value information for ndb_log_bin

Property	Value
Name	`ndb_log_bin`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	No
Scope	Both
Dynamic	Yes
Type	
Default, Range	ON (Version: 8.0)
Notes	DESCRIPTION: Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with --log-bin.

Causes updates to `NDB` tables to be written to the binary log. The setting for this variable has no effect if binary logging is not already enabled on the server using `log_bin`. In NDB 8.0.16 and later, `ndb_log_bin` defaults to 0 (FALSE).

- `ndb_log_binlog_index`

Table 22.248 Type and value information for ndb_log_binlog_index

Property	Value
Name	`ndb_log_binlog_index`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	No
Scope	Global
Dynamic	Yes
Type	
Default, Range	ON (Version: 8.0)

Property	Value
Notes	DESCRIPTION: Insert mapping between epochs and binary log positions into the ndb_binlog_index table. Defaults to ON. Effective only if binary logging is enabled on the server.

Causes a mapping of epochs to positions in the binary log to be inserted into the `ndb_binlog_index` table. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. (In addition, `ndb_log_bin` must not be disabled.) `ndb_log_binlog_index` defaults to `1` (`ON`); normally, there is never any need to change this value in a production environment.

- `ndb_log_empty_epochs`

Table 22.249 Type and value information for ndb_log_empty_epochs

Property	Value
Name	`ndb_log_empty_epochs`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	OFF (Version: 8.0)
Notes	DESCRIPTION: When enabled, epochs in which there were no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled

When this variable is set to 0, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

- `ndb_log_empty_update`

Table 22.250 Type and value information for ndb_log_empty_update

Property	Value
Name	`ndb_log_empty_update`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	OFF (Version: 8.0)
Notes	DESCRIPTION: When enabled, updates which produce no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled

When this variable is set to `ON` (`1`), update transactions with no changes are written to the binary log, even when `--log-slave-updates` is enabled.

- `ndb_log_exclusive_reads`

Table 22.251 Type and value information for ndb_log_exclusive_reads

Property	Value
Name	`ndb_log_exclusive_reads`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Both
Dynamic	Yes
Type	
Default, Range	0 (Version: 8.0)
Notes	DESCRIPTION: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts

This variable determines whether primary key reads are logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. To enable these locks, set the value of `ndb_log_exclusive_reads` to 1. 0, which disables such locking, is the default.

For more information, see Read conflict detection and resolution.

- `ndb_log_orig`

Table 22.252 Type and value information for ndb_log_orig

Property	Value
Name	`ndb_log_orig`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	No
Type	
Default, Range	OFF (Version: 8.0)
Notes	DESCRIPTION: Whether the id and epoch of the originating server are recorded in the mysql.ndb_binlog_index table. Set using the --ndb-log-orig option when starting mysqld.

Shows whether the originating server ID and epoch are logged in the `ndb_binlog_index` table. Set using the `--ndb-log-orig` server option.

- `ndb_log_transaction_id`

Table 22.253 Type and value information for ndb_log_transaction_id

Property	Value
Name	ndb_log_transaction_id
Command Line	No
System Variable	Yes
Status Variable	No
Option File	No
Scope	Global
Dynamic	No
Type	
Default, Range	OFF (Version: 8.0)
Notes	DESCRIPTION: Whether NDB transaction IDs are written into the binary log (Read-only.)

This read-only, Boolean system variable shows whether a slave `mysqld` writes NDB transaction IDs in the binary log (required to use “active-active” NDB Cluster Replication with `NDB$EPOCH_TRANS()` conflict detection). To change the setting, use the `--ndb-log-transaction-id` option.

`ndb_log_transaction_id` is not supported in mainline MySQL Server 8.0.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `ndb_optimized_node_selection`

Table 22.254 Type and value information for ndb_optimized_node_selection

Property	Value
Name	ndb_optimized_node_selection
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	No
Type	
Default, Range	ON (Version: 8.0)
Default, Range	3 / 0 - 3 (Version: NDB 8.0)
Notes	DESCRIPTION: Determines how an SQL node chooses a cluster data node to use as transaction coordinator

There are two forms of optimized node selection, described here:

1. The SQL node uses *promixity* to determine the transaction coordinator; that is, the “closest” data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`; SCI connection; TCP connection from a host other than `localhost`.

2. The SQL thread uses *distribution awareness* to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the

transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values `0`, `1`, `2`, or `3`. `3` is the default. These values affect node selection as follows:

- `0`: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node.
- `1`: Proximity to the SQL node is used to determine the transaction coordinator.
- `2`: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to `0`.
- `3`: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior.)

Proximity is determined as follows:

1. Start with the value set for the `Group` parameter (default 55).
2. For an API node sharing the same host with other API nodes, decrement the value by 1. Assuming the default value for `Group`, the effective value for data nodes on same host as the API node is 54, and for remote data nodes 55.
3. Setting `ndb_data_node_neighbour` further decreases the effective `Group` value by 50, causing this node to be regarded as the nearest node. This is needed only when all data nodes are on hosts other than that hosts the API node and it is desirable to dedicate one of them to the API node. In normal cases, the default adjustment described previously is sufficient.

Frequent changes in `ndb_data_node_neighbour` are not advisable, since this changes the state of the cluster connection and thus may disrupt the selection algorithm for new transactions from each thread until it stablilizes.

- `ndb_read_backup`

Table 22.255 Type and value information for ndb_read_backup

Property	Value
Name	`ndb_read_backup`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	OFF (Version: NDB 8.0)
Notes	DESCRIPTION: Enable read from any replica

Enable read from any replica for any `NDB` table subsequently created.

- `ndb_recv_thread_activation_threshold`

Table 22.256 Type and value information for ndb_recv_thread_activation_threshold

Property	Value
Name	ndb_recv_thread_activation_threshold
Command Line	No
System Variable	No
Status Variable	No
Option File	No
Scope	
Dynamic	No
Type	
Default, Range	8 / 0 (MIN_ACTIVATION_THRESHOLD) - 16 (MAX_ACTIVATION_THRESHOLD) (Version: NDB 8.0)
Notes	DESCRIPTION: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads)

When this number of concurrently active threads is reached, the receive thread takes over polling of the cluster connection.

This variable is global in scope. It can also be set on startup using the `--ndb-recv-thread-activation-threshold` option.

- `ndb_recv_thread_cpu_mask`

Table 22.257 Type and value information for ndb_recv_thread_cpu_mask

Property	Value
Name	ndb_recv_thread_cpu_mask
Command Line	No
System Variable	Yes
Status Variable	No
Option File	No
Scope	Global
Dynamic	Yes
Type	
Default, Range	[empty] (Version: 8.0)
Notes	DESCRIPTION: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.

CPU mask for locking receiver threads to specific CPUs. This is specified as a hexadecimal bitmask; for example, `0x33` means that one CPU is used per receiver thread. An empty string is the default; setting `ndb_recv_thread_cpu_mask` to this value removes any receiver thread locks previously set.

This variable is global in scope. It can also be set on startup using the `--ndb-recv-thread-cpu-mask` option.

- `ndb_report_thresh_binlog_epoch_slip`

Table 22.258 Type and value information for ndb_report_thresh_binlog_epoch_slip

Property	Value
Name	ndb_report_thresh_binlog_epoch_slip
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	3 / 0 - 256 (Version: 8.0)
Default, Range	10 / 0 - 256 (Version: NDB 8.0)
Notes	DESCRIPTION: NDB 7.5.4 and later: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates BUFFERED_EPOCHS_OVER_THRESHOLD event buffer status message; prior to NDB 7.5.4: Threshold for number of epochs to lag behind before reporting binary log status

This represents the threshold for the number of epochs completely buffered in the event buffer, but not yet consumed by the binlog injector thread. When this degree of slippage (lag) is exceeded, an event buffer status message is reported, with `BUFFERED_EPOCHS_OVER_THRESHOLD` supplied as the reason (see Section 22.5.7.3, "Event Buffer Reporting in the Cluster Log"). Slip is increased when an epoch is received from data nodes and buffered completely in the event buffer; it is decreased when an epoch is consumed by the binlog injector thread, it is reduced. Empty epochs are buffered and queued, and so included in this calculation only when this is enabled using the `Ndb::setEventBufferQueueEmptyEpoch()` method from the NDB API.

- `ndb_report_thresh_binlog_mem_usage`

Table 22.259 Type and value information for ndb_report_thresh_binlog_mem_usage

Property	Value
Name	ndb_report_thresh_binlog_mem_usage
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	10 / 0 - 10 (Version: 8.0)
Notes	DESCRIPTION: This is a threshold on the percentage of free memory remaining before reporting binary log status

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of `10` (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message is sent to the cluster log.

- ndb_row_checksum

Table 22.260 Type and value information for ndb_row_checksum

Property	Value
Name	ndb_row_checksum
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	boolean
Default, Range	1 / 0 - 1 (Version: NDB 8.0)
Notes	DESCRIPTION: When enabled, set row checksums; enabled by default

Traditionally, NDB has created tables with row checksums, which checks for hardware issues at the expense of performance. Setting ndb_row_checksum to 0 means that row checksums are *not* used for new or altered tables, which has a significant impact on performance for all types of queries. This variable is set to 1 by default, to provide backward-compatible behavior.

- slave_allow_batching

Table 22.261 Type and value information for slave_allow_batching

Property	Value
Name	slave_allow_batching
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	off (Version: 8.0)
Notes	DESCRIPTION: Turns update batching on and off for a replication slave

Whether or not batched updates are enabled on NDB Cluster replication slaves.

Setting this variable has an effect only when using replication with the NDB storage engine; in MySQL Server 8.0, it is present but does nothing. For more information, see Section 22.6.6, “Starting NDB Cluster Replication (Single Replication Channel)”.

- ndb_show_foreign_key_mock_tables

Table 22.262 Type and value information for ndb_show_foreign_key_mock_tables

Property	Value
Name	ndb_show_foreign_key_mock_tables

Property	Value
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	OFF (Version: 8.0)
Notes	DESCRIPTION: Show the mock tables used to support foreign_key_checks=0

Show the mock tables used by `NDB` to support `foreign_key_checks=0`. When this is enabled, extra warnings are shown when creating and dropping the tables. The real (internal) name of the table can be seen in the output of `SHOW CREATE TABLE`.

- `ndb_slave_conflict_role`

Table 22.263 Type and value information for ndb_slave_conflict_role

Property	Value
Name	`ndb_slave_conflict_role`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	Yes
Type	
Default, Range	NONE / NONE, PRIMARY, SECONDARY, PASS (Version: 8.0)
Notes	DESCRIPTION: Role for slave to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when slave SQL thread is stopped. See documentation for further information.

Determine the role of this SQL node (and NDB Cluster) in a circular (“active-active”) replication setup. `ndb_slave_conflict_role` can take any one of the values `PRIMARY`, `SECONDARY`, `PASS`, or `NULL` (the default). The slave SQL thread must be stopped before you can change `ndb_slave_conflict_role`. In addition, it is not possible to change directly between `PASS` and either of `PRIMARY` or `SECONDARY` directly; in such cases, you must ensure that the SQL thread is stopped, then execute `SET @@GLOBAL.ndb_slave_conflict_role = 'NONE'` first.

For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `ndb_table_no_logging`

Table 22.264 Type and value information for ndb_table_no_logging

Property	Value
Name	`ndb_table_no_logging`
Command Line	No

Property	Value
System Variable	Yes
Status Variable	No
Option File	No
Scope	Session
Dynamic	Yes
Type	
Default, Range	FALSE (Version: 8.0)
Notes	DESCRIPTION: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDBCLUSTER persists for the lifetime of the table.

When this variable is set to `ON` or `1`, it causes `NDB` tables not to be checkpointed to disk. More specifically, this setting applies to tables which are created or altered using `ENGINE NDB` when `ndb_table_no_logging` is enabled, and continues to apply for the lifetime of the table, even if `ndb_table_no_logging` is later changed. Suppose that `A`, `B`, `C`, and `D` are tables that we create (and perhaps also alter), and that we also change the setting for `ndb_table_no_logging` as shown here:

```
SET @@ndb_table_no_logging = 1;

CREATE TABLE A ... ENGINE NDB;

CREATE TABLE B ... ENGINE MYISAM;
CREATE TABLE C ... ENGINE MYISAM;

ALTER TABLE B ENGINE NDB;

SET @@ndb_table_no_logging = 0;

CREATE TABLE D ... ENGINE NDB;
ALTER TABLE C ENGINE NDB;

SET @@ndb_table_no_logging = 1;
```

After the previous sequence of events, tables `A` and `B` are not checkpointed; `A` was created with `ENGINE NDB` and B was altered to use `NDB`, both while `ndb_table_no_logging` was enabled. However, tables `C` and `D` are logged; `C` was altered to use `NDB` and `D` was created using `ENGINE NDB`, both while `ndb_table_no_logging` was disabled. Setting `ndb_table_no_logging` back to `1` or `ON` does *not* cause table `C` or `D` to be checkpointed.

Note

`ndb_table_no_logging` has no effect on the creation of `NDB` table schema files; to suppress these, use `ndb_table_temporary` instead.

- `ndb_table_temporary`

Table 22.265 Type and value information for ndb_table_temporary

Property	Value
Name	`ndb_table_temporary`
Command Line	No
System Variable	Yes

Property	Value
Status Variable	No
Option File	No
Scope	Session
Dynamic	Yes
Type	
Default, Range	FALSE (Version: 8.0)
Notes	DESCRIPTION: NDB tables are not persistent on disk: no schema files are created and the tables are not logged

When set to `ON` or `1`, this variable causes `NDB` tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

Note

Setting this variable currently has no effect. This is a known issue; see Bug #34036.

- `ndb_use_copying_alter_table`

Table 22.266 Type and value information for ndb_use_copying_alter_table

Property	Value
Name	`ndb_use_copying_alter_table`
Command Line	No
System Variable	Yes
Status Variable	No
Option File	No
Scope	Both
Dynamic	No
Type	
Notes	DESCRIPTION: Use copying ALTER TABLE operations in NDB Cluster

Forces `NDB` to use copying of tables in the event of problems with online `ALTER TABLE` operations. The default value is `OFF`.

- `ndb_use_exact_count`

Table 22.267 Type and value information for ndb_use_exact_count

Property	Value
Name	`ndb_use_exact_count`
Command Line	No
System Variable	Yes
Status Variable	No
Option File	No
Scope	Both
Dynamic	Yes
Type	

Property	Value
Default, Range	ON (Version: 8.0)
Default, Range	OFF (Version: NDB 8.0)
Notes	DESCRIPTION: Use exact row count when planning queries

Forces `NDB` to use a count of records during `SELECT COUNT(*)` query planning to speed up this type of query. The default value is `OFF`, which allows for faster queries overall.

- `ndb_use_transactions`

Table 22.268 Type and value information for ndb_use_transactions

Property	Value
Name	`ndb_use_transactions`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Both
Dynamic	Yes
Type	
Default, Range	ON (Version: 8.0)
Notes	DESCRIPTION: Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query

You can disable `NDB` transaction support by setting this variable's values to `OFF` (not recommended). The default is `ON`.

- `ndb_version`

Table 22.269 Type and value information for ndb_version

Property	Value
Name	`ndb_version`
Command Line	No
System Variable	Yes
Status Variable	No
Option File	No
Scope	Global
Dynamic	No
Type	
Default, Range	(Version: 8.0)
Notes	DESCRIPTION: Shows build and NDB engine version as an integer

`NDB` engine version, as a composite integer.

- `ndb_version_string`

Table 22.270 Type and value information for ndb_version_string

Property	Value
Name	ndb_version_string
Command Line	No
System Variable	Yes
Status Variable	No
Option File	No
Scope	Global
Dynamic	No
Type	
Default, Range	(Version: 8.0)
Notes	DESCRIPTION: Shows build information including NDB engine version in ndb-x.y.z format

NDB engine version in ndb-*x.y.z* format.

- server_id_bits

Table 22.271 Type and value information for server_id_bits

Property	Value
Name	server_id_bits
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	Yes
Scope	Global
Dynamic	No
Type	
Default, Range	32 / 7 - 32 (Version: 8.0)
Notes	DESCRIPTION: The effective value of server_id if the server was started with the --server-id-bits option set to a nondefault value

The effective value of server_id if the server was started with the --server-id-bits option set to a nondefault value.

If the value of server_id greater than or equal to 2 to the power of server_id_bits, mysqld refuses to start.

This system variable is supported only by NDB Cluster. server_id_bits is not supported by the standard MySQL Server.

- transaction_allow_batching

Table 22.272 Type and value information for transaction_allow_batching

Property	Value
Name	transaction_allow_batching
Command Line	No

Property	Value
System Variable	Yes
Status Variable	No
Option File	No
Scope	Session
Dynamic	Yes
Type	
Default, Range	FALSE (Version: 8.0)
Notes	DESCRIPTION: Allows batching of statements within a transaction. Disable AUTOCOMMIT to use.

When set to `1` or `ON`, this variable enables batching of statements within the same transaction. To use this variable, `autocommit` must first be disabled by setting it to `0` or `OFF`; otherwise, setting `transaction_allow_batching` has no effect.

It is safe to use this variable with transactions that performs writes only, as having it enabled can lead to reads from the “before” image. You should ensure that any pending transactions are committed (using an explicit `COMMIT` if desired) before issuing a `SELECT`.

Important

`transaction_allow_batching` should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable is currently supported for NDB Cluster only.

The system variables in the following list all relate to the `ndbinfo` information database.

- `ndbinfo_database`

Table 22.273 Type and value information for ndbinfo_database

Property	Value
Name	`ndbinfo_database`
Command Line	No
System Variable	Yes
Status Variable	No
Option File	No
Scope	Global
Dynamic	No
Type	
Default, Range	ndbinfo (Version: 8.0)
Notes	DESCRIPTION: The name used for the NDB information database; read only

Shows the name used for the `NDB` information database; the default is `ndbinfo`. This is a read-only variable whose value is determined at compile time; you can set it by starting the server using `--ndbinfo-database=`*`name`*, which sets the value shown for this variable but does not actually change the name used for the NDB information database.

- `ndbinfo_max_bytes`

Table 22.274 Type and value information for ndbinfo_max_bytes

Property	Value
Name	ndbinfo_max_bytes
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	No
Scope	Both
Dynamic	Yes
Type	
Default, Range	0 / - (Version: 8.0)
Notes	DESCRIPTION: Used for debugging only

Used in testing and debugging only.

- ndbinfo_max_rows

Table 22.275 Type and value information for ndbinfo_max_rows

Property	Value
Name	ndbinfo_max_rows
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	No
Scope	Both
Dynamic	Yes
Type	
Default, Range	10 / - (Version: 8.0)
Notes	DESCRIPTION: Used for debugging only

Used in testing and debugging only.

- ndbinfo_offline

Table 22.276 Type and value information for ndbinfo_offline

Property	Value
Name	ndbinfo_offline
Command Line	No
System Variable	Yes
Status Variable	No
Option File	No
Scope	Global
Dynamic	Yes
Type	
Default, Range	OFF (Version: 8.0)

Property	Value
Notes	DESCRIPTION: Put the ndbinfo database into offline mode, in which no rows are returned from tables or views

Place the `ndbinfo` database into offline mode, in which tables and views can be opened even when they do not actually exist, or when they exist but have different definitions in `NDB`. No rows are returned from such tables (or views).

- `ndbinfo_show_hidden`

Table 22.277 Type and value information for ndbinfo_show_hidden

Property	Value
Name	`ndbinfo_show_hidden`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	No
Scope	Both
Dynamic	Yes
Type	
Default, Range	OFF (Version: 8.0)
Notes	DESCRIPTION: Whether to show ndbinfo internal base tables in the mysql client. The default is OFF.

Whether or not the `ndbinfo` database's underlying internal tables are shown in the `mysql` client. The default is `OFF`.

- `ndbinfo_table_prefix`

Table 22.278 Type and value information for ndbinfo_table_prefix

Property	Value
Name	`ndbinfo_table_prefix`
Command Line	Yes
System Variable	Yes
Status Variable	No
Option File	No
Scope	Both
Dynamic	Yes
Type	
Default, Range	ndb$ (Version: 8.0)
Notes	DESCRIPTION: The prefix to use for naming ndbinfo internal base tables

The prefix used in naming the ndbinfo database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is `ndb$`. You can start the server with the `--ndbinfo-table-prefix` option, but this merely sets the variable and does not change the actual prefix used to name the hidden base tables; the prefix itself is determined at compile time.

- `ndbinfo_version`

  Table 22.279 Type and value information for ndbinfo_version

Property	Value
Name	`ndbinfo_version`
Command Line	No
System Variable	Yes
Status Variable	No
Option File	No
Scope	Global
Dynamic	No
Type	
Default, Range	(Version: 8.0)
Notes	DESCRIPTION: The version of the ndbinfo engine; read only

  Shows the version of the `ndbinfo` engine in use; read-only.

NDB Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to NDB Cluster and the `NDB` storage engine. For status variables not specific to NDB Cluster, and for general information on using status variables, see Section 5.1.10, “Server Status Variables”.

- `Handler_discover`

  The MySQL server can ask the `NDBCLUSTER` storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- `Ndb_api_bytes_sent_count_session`

  Amount of data (in bytes) sent to the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_bytes_sent_count_slave`

  Amount of data (in bytes) sent to the data nodes by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_bytes_sent_count`

  Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_bytes_received_count_session`

  Amount of data (in bytes) received from the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_bytes_received_count_slave`

  Amount of data (in bytes) received from the data nodes by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_bytes_received_count`

  Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_event_data_count_injector`

  The number of row change events received by the NDB binlog injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_event_data_count`

  The number of row change events received by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_event_nondata_count_injector`

  The number of events received, other than row change events, by the NDB binary log injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_event_nondata_count`

  The number of events received, other than row change events, by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_event_bytes_count_injector`

  The number of bytes of events received by the NDB binlog injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_event_bytes_count`

  The number of bytes of events received by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_pk_op_count_session`

  The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_pk_op_count_slave`

  The number of operations by this slave based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_pk_op_count`

  The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_pruned_scan_count_session`

  The number of scans in this client session that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_pruned_scan_count_slave`

The number of scans by this slave that have been pruned to a single partition.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_pruned_scan_count`

  The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_range_scan_count_session`

  The number of range scans that have been started in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_range_scan_count_slave`

  The number of range scans that have been started by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_range_scan_count`

  The number of range scans that have been started by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_read_row_count_session`

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_read_row_count_slave`

  The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_read_row_count`

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_scan_batch_count_session`

  The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_scan_batch_count_slave`

  The number of batches of rows received by this slave. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_scan_batch_count`

  The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_table_scan_count_session`

  The number of table scans that have been started in this client session, including scans of internal tables,.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_table_scan_count_slave`

  The number of table scans that have been started by this slave, including scans of internal tables,.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_table_scan_count`

  The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables,.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_trans_abort_count_session`

  The number of transactions aborted in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_trans_abort_count_slave`

  The number of transactions aborted by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_trans_abort_count`

  The number of transactions aborted by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_trans_close_count_session`

  The number of transactions closed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_trans_close_count_slave`

  The number of transactions closed by this slave. This value may be greater than the sum of `Ndb_api_trans_commit_count_slave` and `Ndb_api_trans_abort_count_slave`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_trans_close_count`

  The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit_count` and `Ndb_api_trans_abort_count`, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_trans_commit_count_session`

  The number of transactions committed in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_trans_commit_count_slave`

  The number of transactions committed by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_trans_commit_count`

  The number of transactions committed by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_trans_local_read_row_count_session`

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_trans_local_read_row_count_slave`

  The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_trans_local_read_row_count`

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_trans_start_count_session`

  The number of transactions started in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_trans_start_count_slave`

  The number of transactions started by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_trans_start_count`

  The number of transactions started by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_uk_op_count_session`

  The number of operations in this client session based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_uk_op_count_slave`

  The number of operations by this slave based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_uk_op_count`

  The number of operations by this MySQL Server (SQL node) based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_wait_exec_complete_count_session`

  The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_wait_exec_complete_count_slave`

  The number of times a thread has been blocked by this slave while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_wait_exec_complete_count`

  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_wait_meta_request_count_session`

  The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_wait_meta_request_count_slave`

  The number of times a thread has been blocked by this slave waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_wait_meta_request_count`

  The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_wait_nanos_count_session`

  Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_wait_nanos_count_slave`

  Total time (in nanoseconds) spent by this slave waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_wait_nanos_count`

  Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_wait_scan_result_count_session`

  The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_wait_scan_result_count_slave`

  The number of times a thread has been blocked by this slave while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_api_wait_scan_result_count`

  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 22.5.17, “NDB API Statistics Counters and Variables”.

- `Ndb_cluster_node_id`

  If the server is acting as an NDB Cluster node, then the value of this variable its node ID in the cluster.

  If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_config_from_host`

  If the server is part of an NDB Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

  If the server is not part of an NDB Cluster, then the value of this variable is an empty string.

- `Ndb_config_from_port`

  If the server is part of an NDB Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

  If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_conflict_fn_max_del_win`

  Shows the number of times that a row was rejected on the current SQL node due to NDB Cluster Replication conflict resolution using `NDB$MAX_DELETE_WIN()`, since the last time that this `mysqld` was started.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `Ndb_conflict_fn_max`

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this `mysqld` was started.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `Ndb_conflict_fn_old`

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `Ndb_conflict_fn_epoch`

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH()` conflict resolution on a given `mysqld` since the last time it was restarted.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `Ndb_conflict_fn_epoch2`

  Shows the number of rows found to be in conflict in NDB Cluster Replication conflict resolution, when using `NDB$EPOCH2()`, on the master designated as the primary since the last time it was restarted.

  For more information, see NDB$EPOCH2().

- `Ndb_conflict_fn_epoch_trans`

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS()` conflict resolution on a given `mysqld` since the last time it was restarted.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `Ndb_conflict_fn_epoch2_trans`

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS2()` conflict resolution on a given `mysqld` since the last time it was restarted.

  For more information, see NDB$EPOCH2_TRANS().

- `Ndb_conflict_last_conflict_epoch`

  The most recent epoch in which a conflict was detected on this slave. You can compare this value with `Ndb_slave_max_replicated_epoch`; if `Ndb_slave_max_replicated_epoch` is greater than `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.

  See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

- `Ndb_conflict_reflected_op_discard_count`

  When using NDB Cluster Replication conflict resolution, this is the number of reflected operations that were not applied on the secondary, due to encountering an error during execution.

  See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

- `Ndb_conflict_reflected_op_prepare_count`

  When using conflict resolution with NDB Cluster Replication, this status variable contains the number of reflected operations that have been defined (that is, prepared for execution on the secondary).

  See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `Ndb_conflict_refresh_op_count`

  When using conflict resolution with NDB Cluster Replication, this gives the number of refresh operations that have been prepared for execution on the secondary.

  See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

- `Ndb_conflict_last_stable_epoch`

  Number of rows found to be in conflict by a transactional conflict function

See Section 22.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

- `Ndb_conflict_trans_row_conflict_count`

  Used in NDB Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given `mysqld` since the last time it was restarted.

  Currently, the only transactional conflict detection function supported by NDB Cluster is NDB$EPOCH_TRANS(), so this status variable is effectively the same as `Ndb_conflict_fn_epoch_trans`.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `Ndb_conflict_trans_row_reject_count`

  Used in NDB Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only `Ndb_conflict_trans_row_conflict_count`, but any rows in or dependent on conflicting transactions.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `Ndb_conflict_trans_reject_count`

  Used in NDB Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `Ndb_conflict_trans_detect_iter_count`

  Used in NDB Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to `Ndb_conflict_trans_conflict_commit_count`.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `Ndb_conflict_trans_conflict_commit_count`

  Used in NDB Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `Ndb_epoch_delete_delete_count`

  When using delete-delete conflict detection, this is the number of delete-delete conflicts detected, where a delete operation is applied, but the indicated row does not exist.

- `Ndb_execute_count`

  Provides the number of round trips to the `NDB` kernel made by operations.

- `Ndb_last_commit_epoch_server`

  The epoch most recently committed by `NDB`.

- `Ndb_last_commit_epoch_session`

  The epoch most recently committed by this `NDB` client.

- `Ndb_number_of_data_nodes`

If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_pushed_queries_defined`

  The total number of joins pushed down to the NDB kernel for distributed handling on the data nodes.

  Note

  Joins tested using `EXPLAIN` that can be pushed down contribute to this number.

- `Ndb_pushed_queries_dropped`

  The number of joins that were pushed down to the NDB kernel but that could not be handled there.

- `Ndb_pushed_queries_executed`

  The number of joins successfully pushed down to `NDB` and executed there.

- `Ndb_pushed_reads`

  The number of rows returned to `mysqld` from the NDB kernel by joins that were pushed down.

  Note

  Executing `EXPLAIN` on joins that can be pushed down to `NDB` does not add to this number.

- `Ndb_pruned_scan_count`

  This variable holds a count of the number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started where `NDBCLUSTER` was able to use partition pruning.

  Using this variable together with `Ndb_scan_count` can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving only a single data node.

- `Ndb_scan_count`

  This variable holds a count of the total number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started.

- `Ndb_slave_max_replicated_epoch`

  The most recently committed epoch on this slave. You can compare this value with `Ndb_conflict_last_conflict_epoch`; if `Ndb_slave_max_replicated_epoch` is the greater of the two, no conflicts have yet been detected.

  For more information, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

- `Ndb_system_name`

  If this MySQL Server is connected to an NDB cluster, this read-only variable shows the cluster system name. Otherwise, the value is an empty string.

22.3.3.10 NDB Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in an NDB Cluster. Normally it is not necessary to define TCP/IP connections; NDB Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

Note

For an exception to this rule, see Section 22.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”.

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two NDB Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

Important

Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the NDB Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

- `NodeId1`

Table 22.280 This table provides type and value information for the NodeId1 TCP configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	[none]
Range	1 - 255
Restart Type	N

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- `NodeId2`

Table 22.281 This table provides type and value information for the NodeId2 TCP configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	[none]
Range	1 - 255

Property	Value
Restart Type	N

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 22.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- `HostName1`

Table 22.282 This table provides type and value information for the HostName1 TCP configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]
Range	...
Restart Type	N

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `HostName2`

Table 22.283 This table provides type and value information for the HostName1 TCP configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]
Range	...
Restart Type	N

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `OverloadLimit`

Table 22.284 This table provides type and value information for the OverloadLimit TCP configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”, for more information.

- `SendBufferMemory`

Table 22.285 This table provides type and value information for the SendBufferMemory TCP configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	2M
Range	256K - 4294967039 (0xFFFFFEFF)
Restart Type	N

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

If this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory —that is, `TotalSendBufferMemory`) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in NDB Cluster, see Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

The default size of the send buffer is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- `SendSignalId`

Table 22.286 This table provides type and value information for the SendSignalId TCP configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	[see text]
Range	true, false
Restart Type	N

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- `Checksum`

Table 22.287 This table provides type and value information for the Checksum TCP configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean

Property	Value
Default	false
Range	true, false
Restart Type	N

This parameter is a boolean parameter (enabled by setting it to `Y` or `1`, disabled by setting it to `N` or `0`). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- `PreSendChecksum`

Table 22.288 This table provides type and value information for the PreSendChecksum TCP configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	S

If this parameter and `Checksum` are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors. Has no effect if `Checksum` is not also enabled.

- `ReceiveBufferMemory`

Table 22.289 This table provides type and value information for the ReceiveBufferMemory TCP configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	2M
Range	16K - 4294967039 (0xFFFFFEFF)
Restart Type	N

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

The default value of this parameter is 2MB. The minimum possible value is 16KB; the theoretical maximum is 4GB.

- `TCP_RCV_BUF_SIZE`

Table 22.290 This table provides type and value information for the TCP_RCV_BUF_SIZE TCP configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 2G
Restart Type	N

Determines the size of the receive buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- `TCP_SND_BUF_SIZE`

Table 22.291 This table provides type and value information for the TCP_SND_BUF_SIZE TCP configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 2G
Restart Type	N

Determines the size of the send buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- `TCP_MAXSEG_SIZE`

Table 22.292 This table provides type and value information for the TCP_MAXSEG_SIZE TCP configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 2G
Restart Type	N

Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.

- `TcpBind_INADDR_ANY`

  Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

- `Group`

  When `ndb_optimized_node_selection` is enabled, node proximity is used in some cases to select which node to connect to. This parameter can be used to influence proximity by setting it to a lower value, which is interpreted as “closer”. See the description of the system variable for more information.

22.3.3.11 NDB Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[tcp]` section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN. In addition to the usual network connections, the two data nodes are connected

directly using a standard crossover cable, and communicate with one another directly using IP addresses in the `1.1.0.*` address range as shown:

```
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostName1` and `HostName2` parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency.

Note

To take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

22.3.3.12 NDB Cluster Shared-Memory Connections

Communications between NDB cluster nodes are normally handled using TCP/IP. The shared memory (SHM) transporter is distinguished by the fact that signals are transmitted by writing in memory rather than on a socket. The shared-memory transporter (SHM) can improve performance by negating up to 20% of the overhead required by a TCP connection when running an API node (usually an SQL node) and a data node together on the same host. NDB Cluster attempts to use the shared memory transporter and configure it automatically between data nodes and API nodes on the same host. You can enable a shared memory connection explicitly, by setting the `UseShm` data node configuration parameter to `1`. When explicitly defining shared memory as the connection method, it is also necessary to set `HostName` for the data node and `HostName` for the API node, and that these be the same. It is also possible to employ multiple SHM connections in the same NDB cluster, on different hosts, each having one API node and one data node; see later in this section for an exaample of how to do this.

Suppose a cluster is running a data node which has node ID 1 and an SQL node having node ID 51 on the same host computer at 10.0.0.1. To enable an SHM connection between these two nodes, all that is necessary is to insure that the following entries are included in the cluster configuration file:

```
[ndbd]
NodeId=1
HostName=10.0.0.1
UseShm=1
```

```
[mysqld]
NodeId=51
HostName=10.0.0.1
```

Important

The two entries just shown are in addition to any other entries and parameter settings needed by the cluster. A more comlete example is shown later in this section.

Before starting data nodes that use SHM connections, it is also necessary to make sure that the operating system on each computer hosting such a data node has sufficient memory allocated to shared memory segments. See the documentation for your operating platform for information regarding this. In setups where multiple hosts are each running a data node and an API node, it is possible to enable shared memory on all such hosts by setting `UseShm` in the `[ndbd default]` section of the configuration file. This is shown in the example later in this section.

While not strictly required, tuning for all SHM connections in the cluster can be done by setting one or more of the following parameters in the `[shm default]` section of the cluster configuration (`config.ini`) file:

- `ShmSize`: Shared memory size
- `ShmSpinTime`: Time in µs to spin before sleeping
- `SendBufferMemory`: Size of buffer for signals sent from this node, in bytes.
- `SendSignalId`: Indicates that a signal ID is included in each signal sent through the transporter.
- `Checksum`: Indicates that a checksum is included in each signal sent through the transporter.
- `PreSendChecksum`: Checks of the checksum are made prior to sending the signal; Checksum must also be enabled for this to work

This example shows a simple setup with SHM connections definied on multiple hosts, in an NDB Cluster using 3 computers listed here by host name, hosting the node types shown:

1. `10.0.0.0`: The management server
2. `10.0.0.1`: A data node and an SQL node
3. `10.0.0.2`: A data node and an SQL node

In this scenario, each data node communicates with both the management server and the other data node using TCP transporters; each SQL node uses a shared memory transporter to communicate with the data nodes that is local to it, and a TCP transporter to communicate with the remote data node. A basic configuration reflecting this setup is enabled by the config.ini file whose contents are shown here:

```
[ndbd default]
DataDir=/path/to/datadir
UseShm=1

[shm default]
ShmSize=8M
ShmSpintime=200
SendBufferMemory=4M

[tcp default]
SendBufferMemory=8M

[ndb_mgmd]
NodeId=49
Hostname=10.0.0.0
DataDir=/path/to/datadir
```

```
[ndbd]
NodeId=1
Hostname=10.0.0.1
DataDir=/path/to/datadir

[ndbd]
NodeId=2
Hostname=10.0.0.2
DataDir=/path/to/datadir

[mysqld]
NodeId=51
Hostname=10.0.0.1

[mysqld]
NodeId=52
Hostname=10.0.0.2

[api]
[api]
```

Parameters affecting all shared memory transporters are set in the `[shm default]` section; these can be overridden on a per-connection basis in one or more `[shm]` sections. Each such section must be associated with a given SHM connection using `NodeId1` and `NodeId2`; the values required for these parameters are the node IDs of the two nodes connected by the transporter. You can also identify the nodes by host name using `HostName1` and `HostName2`, but these parameters are not required.

The API nodes for which no host names are set use the TCP transporter to communicate with data nodes independent of the hosts on which they are started; the parameters and values set in the `[tcp default]` section of the configuration file apply to all TCP transporters in the cluster.

For optimum performance, you can define a spin time for the SHM transporter (`ShmSpinTime` parameter); this affects both the data node receiver thread and the poll owner (receive thread or user thread) in `NDB`.

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 22.293 NDB Cluster restart types

Symbol	Restart Type	Description
N	Node	The parameter can be updated using a rolling restart (see Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”)
S	System	All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter
I	Initial	Data nodes must be restarted using the `--initial` option

- `Checksum`

  Table 22.294 This table provides type and value information for the Checksum shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	true
Range	true, false
Restart Type	N

This parameter is a boolean (`Y`/`N`) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- `Group`

Table 22.295 This table provides type and value information for the Group shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	35
Range	0-200
Restart Type	N

Determines the group proximity; a smaller value is interpreted as being closer. The default value is sufficient for most conditions.

- `HostName1`

Table 22.296 This table provides type and value information for the HostName1 shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]
Range	...
Restart Type	N

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `HostName2`

Table 22.297 This table provides type and value information for the HostName1 shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]
Range	...
Restart Type	N

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `NodeId1`

Table 22.298 This table provides type and value information for the NodeId1 shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	[none]
Range	1 - 255
Restart Type	N

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `NodeId2`

Table 22.299 This table provides type and value information for the NodeId2 shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	[none]
Range	1 - 255
Restart Type	N

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `NodeIdServer`

Table 22.300 This table provides type and value information for the NodeIdServer shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	[none]
Range	1 - 63
Restart Type	N

Identify the server end of a shared memory connection. By default, this is the node ID of the data node.

- `OverloadLimit`

Table 22.301 This table provides type and value information for the OverloadLimit shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	0

Property	Value
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded. See Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”, and Section 22.5.10.44, “The ndbinfo transporters Table”, for more information.

- `PreSendChecksum`

Table 22.302 This table provides type and value information for the PreSendChecksum shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	S

If this parameter and `Checksum` are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors. Has no effect if `Checksum` is not also enabled.

- `SendBufferMemory`

Table 22.303 This table provides type and value information for the SendBufferMemory shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	2M
Range	256K - 4294967039 (0xFFFFFEFF)
Restart Type	N

Size (in bytes) of the shared shared memory buffer for signals sent from this node using a shared memory connection.

- `SendSignalId`

Table 22.304 This table provides type and value information for the SendSignalId shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- `ShmKey`

Table 22.305 This table provides type and value information for the ShmKey shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value. If `UseShm` is enabled, the shared memory key is calculated automatically by `NDB`.

- `ShmSize`

Table 22.306 This table provides type and value information for the ShmSize shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	4M
Range	64K - 4294967039 (0xFFFFFEFF)
Restart Type	N

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by `ShmSize`. The default value is 4MB.

- `ShmSpinTime`

Table 22.307 This table provides type and value information for the ShmSpinTime shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	integer
Default	0
Range	0 - 2000
Restart Type	S

When receiving, the time to wait before sleeping, in microseconds.

- `SigNum`

Table 22.308 This table provides type and value information for the Signum shared memory configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned

Property	Value
Default	[none]
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This parameter was used formerly to override operating system signal numbers; in NDB 8.0, it is no longer used, and any setting for it is ignored.

22.3.3.13 SCI Transport Connections in NDB Cluster

`[sci]` sections in the `config.ini` file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in NDB Cluster requires specialized hardware as well as specially-built MySQL binaries; compiling such binaries is not supported using an NDB 8.0 distribution.

The following parameters are present in `NDB` source code as well as the output of `ndb_config` and other `NDB` programs, but are currently nonfunctional:

- `NodeId1`

  Table 22.309 This table provides type and value information for the NodeId1 SCI configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	[none]
Range	1 - 255
Restart Type	N

  To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `NodeId2`

  Table 22.310 This table provides type and value information for the NodeId2 SCI configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	numeric
Default	[none]
Range	1 - 255
Restart Type	N

  To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `Host1SciId0`

  Table 22.311 This table provides type and value information for the Host1SciId0 SCI configuration parameter

Property	Value
Version (or later)	NDB 8.0.13

Property	Value
Type or units	unsigned
Default	[none]
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This identifies the SCI node ID on the first Cluster node (identified by `NodeId1`).

- `Host1SciId1`

Table 22.312 This table provides type and value information for the Host1SciId1 SCI configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

- `Host2SciId0`

Table 22.313 This table provides type and value information for the Host2SciId0 SCI configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	[none]
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

This identifies the SCI node ID on the second Cluster node (identified by `NodeId2`).

- `Host2SciId1`

Table 22.314 This table provides type and value information for the Host2SciId1 SCI configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

- `HostName1`

Table 22.315 This table provides type and value information for the HostName1 SCI configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]
Range	...
Restart Type	N

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `HostName2`

Table 22.316 This table provides type and value information for the HostName1 SCI configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	name or IP address
Default	[none]
Range	...
Restart Type	N

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `SharedBufferSize`

Table 22.317 This table provides type and value information for the SharedBufferSize SCI configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	10M
Range	64K - 4294967039 (0xFFFFFEFF)
Restart Type	N

Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the `ndbd` process.

- `SendLimit`

Table 22.318 This table provides type and value information for the SendLimit SCI configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	unsigned
Default	8K
Range	128 - 32K
Restart Type	N

A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.

- `SendSignalId`

Table 22.319 This table provides type and value information for the SendSignalId SCI configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	true
Range	true, false
Restart Type	N

To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- `Checksum`

Table 22.320 This table provides type and value information for the Checksum SCI configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	boolean
Default	false
Range	true, false
Restart Type	N

This parameter is a boolean value, and is disabled by default. When `Checksum` is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- `OverloadLimit`

Table 22.321 This table provides type and value information for the OverloadLimit SCI configuration parameter

Property	Value
Version (or later)	NDB 8.0.13
Type or units	bytes
Default	0
Range	0 - 4294967039 (0xFFFFFEFF)
Restart Type	N

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded. See Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”, for more information.

22.3.3.14 Configuring NDB Cluster Send Buffer Parameters

The `NDB` kernel employs a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can accomplished by setting the following parameters:

- **TotalSendBufferMemory.** This parameter can be set for all types of NDB Cluster nodes—that is, it can be set in the `[ndbd]`, `[mgm]`, and `[api]` (or `[mysql]`) sections of the `config.ini` file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

  To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

  Table 22.322 Transporter types with maximum send buffer sizes

Transporter	Maximum Send Buffer Size (bytes)
TCP	`SendBufferMemory` (default = 2M)
SCI	`SendLimit` (default = 8K) plus 16K
SHM	20K

  This enables existing configurations to function in close to the same way as they did with NDB Cluster 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (`Send Buffers overloaded in NDB kernel`) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as `SendBufferMemory * 0.8` for a given connection. The maximum value for this parameter is 4G.

- **SendBufferMemory.** This value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by `TotalSendBufferMemory`. However, the sum of `SendBufferMemory` for all configured transporters may be greater than the `TotalSendBufferMemory` that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

You can use the `ndbinfo.transporters` table to monitor send buffer memory usage, and to detect slowdown and overload conditions that can adversely affect performance.

22.3.4 Using High-Speed Interconnects with NDB Cluster

Even before design of `NDBCLUSTER` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDBCLUSTER` was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The NDB Cluster codebase provides for four different transporters:

- *TCP/IP using 100 Mbps or gigabit Ethernet*, as discussed in Section 22.3.3.10, “NDB Cluster TCP/IP Connections”.
- *Direct (machine-to-machine) TCP/IP*; although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for NDB Cluster. See Section 22.3.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”, for details.
- *Shared memory (SHM)*. For more information about SHM, see Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”.
- *Scalable Coherent Interface (SCI)*. For more information about SCI, see Section 22.3.3.13, “SCI Transport Connections in NDB Cluster”.

Note

Using SCI transporters in NDB Cluster requires specialized hardware, software, and MySQL binaries not available with NDB 8.0.

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with NDB Cluster.

We are working to make sure that communication with the `ndbd` process is made in “chunks” that are as large as possible because this benefits all types of data transmission.

22.4 NDB Cluster Programs

Using and managing an NDB Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in an NDB Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the NDB Cluster data, management, and SQL node processes (`ndbd`, `ndbmtd`, `ndb_mgmd`, and `mysqld`) and the management client (`ndb_mgm`).

Information about the program `ndb_setup.py`, used to start the NDB Cluster Auto-Installer, is also included in this section. You should be aware that Section 22.4.26, “`ndb_setup.py` — Start browser-based Auto-Installer for NDB Cluster”, contains information about the command-line client only; for information about using the GUI installer spawned by this program to configure and deploy an NDB Cluster, see The NDB Cluster Auto-Installer (NDB 7.5).

For information about using `mysqld` as an NDB Cluster process, see Section 22.5.4, “MySQL Server Usage for NDB Cluster”.

Other `NDB` utility, diagnostic, and example programs are included with the NDB Cluster distribution. These include `ndb_restore`, `ndb_show_tables`, and `ndb_config`. These programs are also covered in this section.

The final portion of this section contains tables of options that are common to all the various NDB Cluster programs.

22.4.1 ndbd — The NDB Cluster Data Node Daemon

ndbd is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In an NDB Cluster, a set of ndbd processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

The following table includes command options specific to the NDB Cluster data node program ndbd. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndbd), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.323 Command-line options for the ndbd program

Format	Description	Added, Deprecated, or Removed
--bind-address=name	Local bind address	All NDB 8.0 releases
--connect-delay=#	Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts	All NDB 8.0 releases
--connect-retries=#	Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries)	All NDB 8.0 releases
--connect-retry-delay=#	Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts	All NDB 8.0 releases
--daemon, -d	Start ndbd as daemon (default); override with --nodaemon	All NDB 8.0 releases
--foreground	Run ndbd in foreground, provided for debugging purposes (implies --nodaemon)	All NDB 8.0 releases
--initial	Perform initial start of ndbd, including cleaning the file system. Consult the documentation before using this option	All NDB 8.0 releases
--initial-start	Perform partial initial start (requires --nowait-nodes)	All NDB 8.0 releases
--install[=name]	Used to install the data node process as a Windows service. Does not apply on non-Windows platforms.	All NDB 8.0 releases
--logbuffer-size=#	Control size of log buffer. For use when debugging with many log messages being generated; default is sufficient for normal operations.	All NDB 8.0 releases
--nostart, -n	Don't start ndbd immediately; ndbd waits for command to start from ndb_mgmd	All NDB 8.0 releases

Format	Description	Added, Deprecated, or Removed
--nodaemon	Do not start ndbd as daemon; provided for testing purposes	All NDB 8.0 releases
--nowait-nodes=list	Do not wait for these data nodes to start (takes comma-separated list of node IDs). Also requires --ndb-nodeid to be used.	All NDB 8.0 releases
--remove[=name]	Used to remove a data node process that was previously installed as a Windows service. Does not apply on non-Windows platforms.	All NDB 8.0 releases
--verbose, -v	Causes the data log to write extra debugging information to the node log.	All NDB 8.0 releases

Note

All of these options also apply to the multithreaded version of this program (ndbmtd) and you may substitute "ndbmtd" for "ndbd" wherever the latter occurs in this section.

- --bind-address

Property	Value
Command-Line Format	--bind-address=name
Type	String
Default Value	

Causes ndbd to bind to a specific network interface (host name or IP address). This option has no default value.

- --connect-delay=#

Property	Value
Command-Line Format	--connect-delay=#
Deprecated	Yes
Type	Numeric
Default Value	5
Minimum Value	0
Maximum Value	3600

Determines the time to wait between attempts to contact a management server when starting (the number of attempts is controlled by the --connect-retries option). The default is 5 seconds.

This option is deprecated, and is subject to removal in a future release of NDB Cluster. Use --connect-retry-delay instead.

- --connect-retries=#

Property	Value
Command-Line Format	--connect-retries=#

Property	Value
Type	Numeric
Default Value	12
Minimum Value	0
Maximum Value	65535

Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries). The default is 12 attempts. The time to wait between attempts is controlled by the --connect-retry-delay option.

- --connect-retry-delay=#

Property	Value
Command-Line Format	--connect-retry-delay=#
Type	Numeric
Default Value	5
Minimum Value	0
Maximum Value	4294967295

Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the --connect-retries option). The default is 5 seconds.

This option takes the place of the --connect-delay option, which is now deprecated and subject to removal in a future release of NDB Cluster.

- --daemon, -d

Property	Value
Command-Line Format	--daemon
Type	Boolean
Default Value	TRUE

Instructs ndbd or ndbmtd to execute as a daemon process. This is the default behavior. --nodaemon can be used to prevent the process from running as a daemon.

This option has no effect when running ndbd or ndbmtd on Windows platforms.

- --foreground

Property	Value
Command-Line Format	--foreground
Type	Boolean
Default Value	FALSE

Causes ndbd or ndbmtd to execute as a foreground process, primarily for debugging purposes. This option implies the --nodaemon option.

This option has no effect when running ndbd or ndbmtd on Windows platforms.

- --initial

Property	Value
Command-Line Format	--initial

Property	Value
Type	Boolean
Default Value	FALSE

Instructs ndbd to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of ndbd. It also re-creates recovery log files. On some operating systems, this process can take a substantial amount of time.

An --initial start is to be used *only* when starting the ndbd process under very special circumstances; this is because this option causes all files to be removed from the NDB Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of ndbd.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

Warning

To avoid the possibility of eventual data loss, it is recommended that you *not* use the --initial option together with StopOnError = 0. Instead, set StopOnError to 0 in config.ini only after the cluster has been started, then restart the data nodes normally—that is, without the --initial option. See the description of the StopOnError parameter for a detailed explanation of this issue. (Bug #24945638)

Use of this option prevents the StartPartialTimeout and StartPartitionedTimeout configuration parameters from having any effect.

Important

This option does *not* affect either of the following types of files:

- Backup files that have already been created by the affected node
- NDB Cluster Disk Data files (see Section 22.5.13, “NDB Cluster Disk Data Tables”).

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running. This recovery of data occurs automatically, and requires no user intervention in an NDB Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

- --initial-start

Property	Value
Command-Line Format	--initial-start
Type	Boolean
Default Value	FALSE

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as --nowait-nodes.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
shell> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` option.

Important

Do not confuse this option with the `--nowait-nodes` option for `ndb_mgmd`, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

- `--install[=name]`

Property	Value
Command-Line Format	`--install[=name]`
Platform Specific	Windows
Type	String
Default Value	`ndbd`

Causes `ndbd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndbd`. Although it is preferable to specify other `ndbd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other `ndbd` options that affect the starting of data nodes—including `--initial-start`, `--nostart`, and `--nowait-nodes`—together with `--install`, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--logbuffer-size=#`

Property	Value
Command-Line Format	`--logbuffer-size=#`
Type	Integer
Default Value	`32768`
Minimum Value	`2048`
Maximum Value	`4294967295`

Sets the size of the data node log buffer. When debugging with high amounts of extra logging, it is possible for the log buffer to run out of space if there are too many log messages, in which case some log messages can be lost. This should not occur during normal operations.

- `--nodaemon`

Property	Value
Command-Line Format	`--nodaemon`
Type	Boolean
Default Value	`FALSE`

Prevents `ndbd` or `ndbmtd` from executing as a daemon process. This option overrides the `--daemon` option. This is useful for redirecting output to the screen when debugging the binary.

The default behavior for `ndbd` and `ndbmtd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect.

- `--nostart`, `-n`

Property	Value
Command-Line Format	`--nostart`
Type	Boolean
Default Value	`FALSE`

Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper `START` command in the management client (see Section 22.5.2, “Commands in the NDB Cluster Management Client”).

- `--nowait-nodes=`*`node_id_1`*`[, `*`node_id_2`*`[, ...]]`

Property	Value
Command-Line Format	`--nowait-nodes=list`
Type	String
Default Value	

This option takes a list of data nodes which for which the cluster will not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does *not* wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

- `--remove[=`*`name`*`]`

Property	Value
Command-Line Format	`--remove[=name]`
Platform Specific	Windows
Type	String
Default Value	`ndbd`

Causes an ndbd process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to ndbd.

The --remove option has no effect on non-Windows platforms.

- --verbose, -v

  Causes extra debug output to be written to the node log.

  You can also use NODELOG DEBUG ON and NODELOG DEBUG OFF to enable and disable this extra logging while the data node is running.

ndbd generates a set of log files which are placed in the directory specified by DataDir in the config.ini configuration file.

These log files are listed below. *node_id* is and represents the node's unique identifier. For example, ndb_2_error.log is the error log generated by the data node whose node ID is 2.

- ndb_*node_id*_error.log is a file containing records of all crashes which the referenced ndbd process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

  Listings of possible ndbd exit codes and messages generated when a data node process shuts down prematurely can be found in Data Node Error Messages.

Important

The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are *not* listed in chronological order; rather, they correspond to the order of the trace files as determined in the ndb_*node_id*_trace.log.next file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- ndb_*node_id*_trace.log.*trace_id* is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the NDB Cluster development team.

  It is possible to configure the number of these trace files that will be created before old files are overwritten. *trace_id* is a number which is incremented for each successive trace file.

- ndb_*node_id*_trace.log.next is the file that keeps track of the next trace file number to be assigned.

- ndb_*node_id*_out.log is a file containing any data output by the ndbd process. This file is created only if ndbd is started as a daemon, which is the default behavior.

- ndb_*node_id*.pid is a file containing the process ID of the ndbd process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.

- ndb_*node_id*_signal.log is a file used only in debug versions of ndbd, where it is possible to trace all incoming, outgoing, and internal messages with their data in the ndbd process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the .pid file remains in effect even after the process has terminated.

To start ndbd, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See Section 22.3.3.3, “NDB Cluster Connection Strings”, for additional information about this issue. Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”, describes other command-line options which can be used with ndbd. For information about data node configuration parameters, see Section 22.3.3.6, “Defining NDB Cluster Data Nodes”.

When ndbd starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the ndbd process if it is configured to do so. Thus, if you attempt to kill ndbd using the Unix kill command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an ndbd process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the ndbd process. In a multi-processor system performing a large number of operations (including updates), the ndbd process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several ndbd processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 8.0 in a production setting. See Section 22.1.7, “Known Limitations of NDB Cluster”.

22.4.2 ndbinfo_select_all — Select From ndbinfo Tables

ndbinfo_select_all is a client program that selects all rows and columns from one or more tables in the ndbinfo database

Not all ndbinfo tables available in the mysql client can be read by this program. In addition, ndbinfo_select_all can show information about some tables internal to ndbinfo which cannot be accessed using SQL, including the tables and columns metadata tables.

To select from one or more ndbinfo tables using ndbinfo_select_all, it is necessary to supply the names of the tables when invoking the program as shown here:

```
shell> ndbinfo_select_all table_name1  [table_name2] [...]
```

For example:

```
shell> ndbinfo_select_all logbuffers logspaces
== logbuffers ==
node_id log_type        log_id  log_part        total   used    high
5       0       0       0       33554432        262144  0
6       0       0       0       33554432        262144  0
7       0       0       0       33554432        262144  0
8       0       0       0       33554432        262144  0
== logspaces ==
node_id log_type        log_id  log_part        total   used    high
5       0       0       0       268435456       0       0
```

```
5       0       0       1       268435456       0       0
5       0       0       2       268435456       0       0
5       0       0       3       268435456       0       0
6       0       0       0       268435456       0       0
6       0       0       1       268435456       0       0
6       0       0       2       268435456       0       0
6       0       0       3       268435456       0       0
7       0       0       0       268435456       0       0
7       0       0       1       268435456       0       0
7       0       0       2       268435456       0       0
7       0       0       3       268435456       0       0
8       0       0       0       268435456       0       0
8       0       0       1       268435456       0       0
8       0       0       2       268435456       0       0
8       0       0       3       268435456       0       0
shell>
```

The following table includes options that are specific to ndbinfo_select_all. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndbinfo_select_all), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.324 Command-line options for the ndbinfo_select_all program

Format	Description	Added, Deprecated, or Removed
--delay=#	Set the delay in seconds between loops. Default is 5.	All NDB 8.0 releases
--loops=#, -l	Set the number of times to perform the select. Default is 1.	All NDB 8.0 releases
--database=db_name, -d	Name of the database where the table located.	All NDB 8.0 releases
--parallelism=#, -p	Set the degree of parallelism.	All NDB 8.0 releases

- --delay=seconds

Property	Value
Command-Line Format	--delay=#
Type	Numeric
Default Value	5
Minimum Value	0
Maximum Value	MAX_INT

This option sets the number of seconds to wait between executing loops. Has no effect if --loops is set to 0 or 1.

- --loops=number, -l *number*

Property	Value
Command-Line Format	--loops=#
Type	Numeric
Default Value	1
Minimum Value	0

Property	Value
Maximum Value	MAX_INT

This option sets the number of times to execute the select. Use --delay to set the time between loops.

22.4.3 ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)

ndbmtd is a multithreaded version of ndbd, the process that is used to handle all the data in tables using the NDBCLUSTER storage engine. ndbmtd is intended for use on host computers having multiple CPU cores. Except where otherwise noted, ndbmtd functions in the same way as ndbd; therefore, in this section, we concentrate on the ways in which ndbmtd differs from ndbd, and you should consult Section 22.4.1, “ndbd — The NDB Cluster Data Node Daemon”, for additional information about running NDB Cluster data nodes that apply to both the single-threaded and multithreaded versions of the data node process.

Command-line options and configuration parameters used with ndbd also apply to ndbmtd. For more information about these options and parameters, see Section 22.4.1, “ndbd — The NDB Cluster Data Node Daemon”, and Section 22.3.3.6, “Defining NDB Cluster Data Nodes”, respectively.

ndbmtd is also file system-compatible with ndbd. In other words, a data node running ndbd can be stopped, the binary replaced with ndbmtd, and then restarted without any loss of data. (However, when doing this, you must make sure that MaxNoOfExecutionThreads is set to an apppriate value before restarting the node if you wish for ndbmtd to run in multithreaded fashion.) Similarly, an ndbmtd binary can be replaced with ndbd simply by stopping the node and then starting ndbd in place of the multithreaded binary. It is not necessary when switching between the two to start the data node binary using --initial.

Using ndbmtd differs from using ndbd in two key respects:

1. Because ndbmtd runs by default in single-threaded mode (that is, it behaves like ndbd), you must configure it to use multiple threads. This can be done by setting an appropriate value in the config.ini file for the MaxNoOfExecutionThreads configuration parameter or the ThreadConfig configuration parameter. Using MaxNoOfExecutionThreads is simpler, but ThreadConfig offers more flexibility. For more information about these configuration parameters and their use, see Multi-Threading Configuration Parameters (ndbmtd).

2. Trace files are generated by critical errors in ndbmtd processes in a somewhat different fashion from how these are generated by ndbd failures. These differences are discussed in more detail in the next few paragraphs.

Like ndbd, ndbmtd generates a set of log files which are placed in the directory specified by DataDir in the config.ini configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by ndbd.

In the event of a critical error, ndbmtd generates trace files describing what happened just prior to the error' occurrence. These files, which can be found in the data node's DataDir, are useful for analysis of problems by the NDB Cluster Development and Support teams. One trace file is generated for each ndbmtd thread. The names of these files have the following pattern:

```
ndb_node_id_trace.log.trace_id_tthread_id,
```

In this pattern, *node_id* stands for the data node's unique node ID in the cluster, *trace_id* is a trace sequence number, and *thread_id* is the thread ID. For example, in the event of the failure of an ndbmtd process running as an NDB Cluster data node having the node ID 3 and with MaxNoOfExecutionThreads equal to 4, four trace files are generated in the data node's data directory. If the is the first time this node has failed, then these files are named ndb_3_trace.log.1_t1, ndb_3_trace.log.1_t2, ndb_3_trace.log.1_t3, and ndb_3_trace.log.1_t4. Internally, these trace files follow the same format as ndbd trace files.

The ndbd exit codes and messages that are generated when a data node process shuts down prematurely are also used by ndbmtd. See Data Node Error Messages, for a listing of these.

Note

It is possible to use ndbd and ndbmtd concurrently on different data nodes in the same NDB Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

22.4.4 ndb_mgmd — The NDB Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

The following table includes options that are specific to the NDB Cluster management server program ndb_mgmd. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_mgmd), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.325 Command-line options for the ndb_mgmd program

Format	Description	Added, Deprecated, or Removed
--bind-address=host	Local bind address	All NDB 8.0 releases
--config-cache[=TRUE|FALSE]	Enable the management server configuration cache; TRUE by default.	All NDB 8.0 releases
--config-file=file (>=), -f (>=)	Specify the cluster configuration file; in NDB-6.4.0 and later, needs --reload or --initial to override configuration cache if present	All NDB 8.0 releases
--configdir=directory, --config-dir=directory (>=7.0.8)	Specify the cluster management server's configuration cache directory	All NDB 8.0 releases
--daemon, -d	Run ndb_mgmd in daemon mode (default)	All NDB 8.0 releases
--initial	Causes the management server reload its configuration data from the configuration file, bypassing the configuration cache	All NDB 8.0 releases
--install[=name]	Used to install the management server process as a Windows service. Does not apply on non-Windows platforms.	All NDB 8.0 releases
--interactive	Run ndb_mgmd in interactive mode (not officially supported in production; for testing purposes only)	All NDB 8.0 releases
--log-name=name	A name to use when writing messages applying to this node in the cluster log.	All NDB 8.0 releases

Format	Description	Added, Deprecated, or Removed
--mycnf	Read cluster configuration data from the my.cnf file	All NDB 8.0 releases
--no-nodeid-checks	Do not provide any node id checks	All NDB 8.0 releases
--nodaemon	Do not run ndb_mgmd as a daemon	All NDB 8.0 releases
--nowait-nodes=list	Do not wait for these management nodes when starting this management server. Also requires --ndb-nodeid to be used.	All NDB 8.0 releases
--print-full-config, -P	Print full configuration and exit	All NDB 8.0 releases
--reload	Causes the management server to compare the configuration file with its configuration cache	All NDB 8.0 releases
--remove[=name]	Used to remove a management server process that was previously installed as a Windows service, optionally specifying the name of the service to be removed. Does not apply on non-Windows platforms.	All NDB 8.0 releases
--verbose, -v	Write additional information to the log.	All NDB 8.0 releases

- `--bind-address=host`

Property	Value
Command-Line Format	`--bind-address=host`
Type	String
Default Value	`[none]`

Causes the management server to bind to a specific network interface (host name or IP address). This option has no default value.

- `--config-cache`

Property	Value
Command-Line Format	`--config-cache[=TRUE|FALSE]`
Type	Boolean
Default Value	`TRUE`

This option, whose default value is `1` (or `TRUE`, or `ON`), can be used to disable the management server's configuration cache, so that it reads its configuration from `config.ini` every time it starts (see Section 22.3.3, “NDB Cluster Configuration Files”). You can do this by starting the `ndb_mgmd` process with any one of the following options:

- `--config-cache=0`
- `--config-cache=FALSE`

- `--config-cache=OFF`
- `--skip-config-cache`

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the `--config-cache` option or the `--skip-config-cache` option is ignored. Therefore, to disable configuration caching, the option should be used the *first* time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has *already* created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with `--skip-config-cache` (or with `--config-cache` set equal to 0, `OFF`, or `FALSE`).

Configuration cache files are normally created in a directory named `mysql-cluster` under the installation directory (unless this location has been overridden using the `--configdir` option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin.seq-number
```

`node-id` is the management server's node ID; *`seq-number`* is a sequence number, beginning with 1. For example, if the management server's node ID is 5, then the first three configuration cache files would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start `ndb_mgmd` with one of the options `--reload` or `--initial` instead of `--skip-config-cache`.

To re-enable the configuration cache, simply restart the management server, but without the `--config-cache` or `--skip-config-cache` option that was used previously to disable the configuration cache.

`ndb_mgmd` does not check for the configuration directory (`--configdir`) or attempts to create one when `--skip-config-cache` is used. (Bug #13428853)

- `--config-file=filename`, `-f filename`

Property	Value
Command-Line Format	`--config-file=file`
Type	File name
Default Value	`[none]`

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

This option has no default value, and is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` or `--initial` option, or because the management server could not find any configuration cache. This option is also read if `ndb_mgmd` was started with `--config-cache=OFF`. See Section 22.3.3, “NDB Cluster Configuration Files”, for more information.

- `--configdir=dir_name`

Property	Value
Command-Line Format	`--configdir=directory`

Property	Value
	`--config-dir=directory`
Type	File name
Default Value	`$INSTALLDIR/mysql-cluster`

Specifies the cluster management server's configuration cache directory. `--config-dir` is an alias for this option.

- `--daemon`, `-d`

Property	Value
Command-Line Format	`--daemon`
Type	Boolean
Default Value	`TRUE`

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

This option has no effect when running `ndb_mgmd` on Windows platforms.

- `--initial`

Property	Value
Command-Line Format	`--initial`
Type	Boolean
Default Value	`FALSE`

Configuration data is cached internally, rather than being read from the cluster global configuration file each time the management server is started (see Section 22.3.3, “NDB Cluster Configuration Files”). Using the `--initial` option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the `--reload` option. First, `--reload` forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, `--reload` does not delete any existing cache files.

If `ndb_mgmd` is invoked with `--initial` but cannot find a global configuration file, the management server cannot start.

When a management server starts, it checks for another management server in the same NDB Cluster and tries to use the other management server's configuration data. This behavior has implications when performing a rolling restart of an NDB Cluster with multiple management nodes. See Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”, for more information.

When used together with the `--config-file` option, the cache is cleared only if the configuration file is actually found.

- `--install[=name]`

Property	Value
Command-Line Format	`--install[=name]`
Platform Specific	Windows
Type	String

Property	Value
Default Value	ndb_mgmd

Causes ndb_mgmd to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to ndb_mgmd. Although it is preferable to specify other ndb_mgmd program options in a my.ini or my.cnf configuration file, it is possible to use them together with --install. However, in such cases, the --install option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the --initial option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other ndb_mgmd options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The --install option has no effect on non-Windows platforms.

- --interactive

Property	Value
Command-Line Format	--interactive
Type	Boolean
Default Value	FALSE

Starts ndb_mgmd in interactive mode; that is, an ndb_mgm client session is started as soon as the management server is running. This option does not start any other NDB Cluster nodes.

- --log-name=*name*

Property	Value
Command-Line Format	--log-name=name
Type	String
Default Value	MgmtSrvr

Provides a name to be used for this node in the cluster log.

- --mycnf

Property	Value
Command-Line Format	--mycnf
Type	Boolean
Default Value	FALSE

Read configuration data from the my.cnf file.

- --no-nodeid-checks

Property	Value
Command-Line Format	--no-nodeid-checks
Type	Boolean
Default Value	FALSE

Do not perform any checks of node IDs.

- --nodaemon

Property	Value
Command-Line Format	--nodaemon
Type	Boolean
Default Value	FALSE

Instructs ndb_mgmd not to start as a daemon process.

The default behavior for ndb_mgmd on Windows is to run in the foreground, making this option unnecessary on Windows platforms.

- --nowait-nodes

Property	Value
Command-Line Format	--nowait-nodes=list
Type	Numeric
Default Value	
Minimum Value	1
Maximum Value	255

When starting an NDB Cluster is configured with two management nodes, each management server normally checks to see whether the other ndb_mgmd is also operational and whether the other management server's configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other ndb_mgmd to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a config.ini file (where we have omitted most of the configuration parameters that are not relevant to this example):

```
[ndbd]
NodeId = 1
HostName = 198.51.100.101

[ndbd]
NodeId = 2
HostName = 198.51.100.102

[ndbd]
NodeId = 3
HostName = 198.51.100.103

[ndbd]
NodeId = 4
HostName = 198.51.100.104

[ndb_mgmd]
NodeId = 10
HostName = 198.51.100.150

[ndb_mgmd]
NodeId = 11
HostName = 198.51.100.151

[api]
NodeId = 20
HostName = 198.51.100.200
```

```
[api]
NodeId = 21
HostName = 198.51.100.201
```

Assume that you wish to start this cluster using only the management server having node ID `10` and running on the host having the IP address 198.51.100.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 198.51.100.150 to enter the following command:

```
shell> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using `--nowait-nodes`, you must also use the `--ndb-nodeid` option to specify the node ID of this `ndb_mgmd` process.

You can then start each of the cluster's data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without restarting the data nodes, you must start each data node with a connection string that references both management servers, like this:

```
shell> ndbd -c 198.51.100.150,198.51.100.151
```

The same is true with regard to the connection string used with any `mysqld` processes that you wish to start as NDB Cluster SQL nodes connected to this cluster. See Section 22.3.3.3, “NDB Cluster Connection Strings”, for more information.

When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` or `ndbmtd` to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same NDB Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

Note

When you later start the “missing” management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

- `--print-full-config`, `-P`

Property	Value
Command-Line Format	`--print-full-config`
Type	Boolean
Default Value	`FALSE`

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file` (`-f`) option.

- `--reload`

Property	Value
Command-Line Format	`--reload`
Type	Boolean
Default Value	`FALSE`

NDB Cluster configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see Section 22.3.3, “NDB Cluster Configuration Files”). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the `--initial` option. First, `--initial` causes all cache files to be deleted. Second, `--initial` forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the `--reload` option is ignored.

When a management server starts, it checks for another management server in the same NDB Cluster and tries to use the other management server's configuration data; `ndb_mgmd` ignores `--reload` unless it is the only management server running. This behavior also has implications when performing a rolling restart of an NDB Cluster with multiple management nodes. See Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”, for more information.

- `--remove{=name]`

Property	Value
Command-Line Format	`--remove[=name]`
Platform Specific	Windows
Type	String
Default Value	`ndb_mgmd`

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

- `--verbose`, `-v`

Property	Value
Command-Line Format	`--verbose`
Type	Boolean
Default Value	`FALSE`

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

It is not strictly necessary to specify a connection string when starting the management server. However, if you are using more than one management server, a connection string should be provided and each node in the cluster should specify its node ID explicitly.

See Section 22.3.3.3, “NDB Cluster Connection Strings”, for information about using connection strings. Section 22.4.4, “`ndb_mgmd` — The NDB Cluster Management Server Daemon”, describes other options for `ndb_mgmd`.

The following files are created or used by ndb_mgmd in its starting directory, and are placed in the DataDir as specified in the config.ini configuration file. In the list that follows, *node_id* is the unique node identifier.

- config.ini is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. Section 22.3, “Configuration of NDB Cluster”, discusses how to set up this file.
- ndb_*node_id*_cluster.log is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in Section 22.5, “Management of NDB Cluster”.

  By default, when the size of the cluster log reaches one million bytes, the file is renamed to ndb_*node_id*_cluster.log.*seq_id*, where *seq_id* is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the LogDestination configuration parameter.
- ndb_*node_id*_out.log is the file used for stdout and stderr when running the management server as a daemon.
- ndb_*node_id*.pid is the process ID file used when running the management server as a daemon.

22.4.5 ndb_mgm — The NDB Cluster Management Client

The ndb_mgm management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by ndb_mgm.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are localhost and 1186, respectively.

The following table includes options that are specific to the NDB Cluster management client program ndb_mgm. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_mgm), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.326 Command-line options for the ndb_mgm program

Format	Description	Added, Deprecated, or Removed
--try-reconnect=#, -t	Set the number of times to retry a connection before giving up; synonym for --connect-retries	All NDB 8.0 releases
--execute=name, -e	Execute command and exit	All NDB 8.0 releases

- --connect-retries=#

Property	Value
Command-Line Format	--connect-retries=#
Type	Numeric
Default Value	3
Minimum Value	0
Maximum Value	4294967295

This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using --connect-retry-delay.

This option is synonymous with the --try-reconnect option, which is now deprecated.

The default for this option this option differs from its default when used with other NDB programs. See Section 22.4.31, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs", for more information.

- --execute=command, -e command

Property	Value
Command-Line Format	--execute=name

This option can be used to send a command to the NDB Cluster management client from the system shell. For example, either of the following is equivalent to executing SHOW in the management client:

```
shell> ndb_mgm -e "SHOW"

shell> ndb_mgm --execute="SHOW"
```

This is analogous to how the --execute or -e option works with the mysql command-line client. See Section 4.2.5, "Using Options on the Command Line".

Note

If the management client command to be passed using this option contains any space characters, then the command *must* be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

- --try-reconnect=*number*

Property	Value
Command-Line Format	--try-reconnect=#
Deprecated	Yes
Type	Numeric
Type	Integer
Default Value	12
Default Value	3
Minimum Value	0
Maximum Value	4294967295

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to *number* before giving up and reporting an error instead.

This option is deprecated and subject to removal in a future release. Use --connect-retries, instead.

Additional information about using ndb_mgm can be found in Section 22.5.2, "Commands in the NDB Cluster Management Client".

22.4.6 ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

This tool can be used to check for and remove orphaned BLOB column parts from NDB tables, as well as to generate a file listing any orphaned parts. It is sometimes useful in diagnosing and repairing corrupted or damaged NDB tables containing BLOB or TEXT columns.

The basic syntax for ndb_blob_tool is shown here:

```
ndb_blob_tool [options] table [column, ...]
```

Unless you use the --help option, you must specify an action to be performed by including one or more of the options --check-orphans, --delete-orphans, or --dump-file. These options cause ndb_blob_tool to check for orphaned BLOB parts, remove any orphaned BLOB parts, and generate a dump file listing orphaned BLOB parts, respectively, and are described in more detail later in this section.

You must also specify the name of a table when invoking ndb_blob_tool. In addition, you can optionally follow the table name with the (comma-separated) names of one or more BLOB or TEXT columns from that table. If no columns are listed, the tool works on all of the table's BLOB and TEXT columns. If you need to specify a database, use the --database (-d) option.

The --verbose option provides additional information in the output about the tool's progress.

The following table includes options that are specific to ndb_blob_tool. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_blob_tool), see Section 22.4.31, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

Table 22.327 Command-line options for the ndb_blob_tool program

Format	Description	Added, Deprecated, or Removed
--check-orphans	Check for orphan blob parts	All NDB 8.0 releases
--database=db_name, -d	Database to find the table in.	All NDB 8.0 releases
--delete-orphans	Delete orphan blob parts	All NDB 8.0 releases
--dump-file=file	Write orphan keys to specified file	All NDB 8.0 releases
--verbose, -v	Verbose output	All NDB 8.0 releases

- --check-orphans

Property	Value
Command-Line Format	--check-orphans

Property	Value
Type	Boolean
Default Value	FALSE

Check for orphaned BLOB parts in NDB Cluster tables.

- `--database=db_name`, `-d`

Property	Value
Command-Line Format	--database=db_name
Type	String
Default Value	[none]

Specify the database to find the table in.

- `--delete-orphans`

Property	Value
Command-Line Format	--delete-orphans
Type	Boolean
Default Value	FALSE

Remove orphaned BLOB parts from NDB Cluster tables.

- `--dump-file=file`

Property	Value
Command-Line Format	--dump-file=file
Type	File name
Default Value	[none]

Writes a list of orphaned BLOB column parts to *file*. The information written to the file includes the table key and BLOB part number for each orphaned BLOB part.

- `--verbose`

Property	Value
Command-Line Format	--verbose
Type	Boolean
Default Value	FALSE

Provide extra information in the tool's output regarding its progress.

Example

First we create an NDB table in the test database, using the CREATE TABLE statement shown here:

```
USE test;

CREATE TABLE btest (
    c0 BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    c1 TEXT,
    c2 BLOB
)   ENGINE=NDB;
```

Then we insert a few rows into this table, using a series of statements similar to this one:

```
INSERT INTO btest VALUES (NULL, 'x', REPEAT('x', 1000));
```

When run with `--check-orphans` against this table, `ndb_blob_tool` generates the following output:

```
shell> ndb_blob_tool --check-orphans --verbose -d test btest
connected
processing 2 blobs
processing blob #0 c1 NDB$BLOB_19_1
NDB$BLOB_19_1: nextResult: res=1
total parts: 0
orphan parts: 0
processing blob #1 c2 NDB$BLOB_19_2
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=1
total parts: 10
orphan parts: 0
disconnected

NDBT_ProgramExit: 0 - OK
```

The tool reports that there are no `NDB` BLOB column parts associated with column `c1`, even though `c1` is a `TEXT` column. This is due to the fact that, in an `NDB` table, only the first 256 bytes of a `BLOB` or `TEXT` column value are stored inline, and only the excess, if any, is stored separately; thus, if there are no values using more than 256 bytes in a given column of one of these types, no `BLOB` column parts are created by `NDB` for this column. See Section 11.8, “Data Type Storage Requirements”, for more information.

22.4.7 ndb_config — Extract NDB Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: an NDB Cluster management node, or its `config.ini` or `my.cnf` file. By default, the management node is the source for the configuration data; to override the default, execute ndb_config with the `--config-file` or `--mycnf` option. It is also possible to use a data node as the source by specifying its node ID with `--config_from_node=`*`node_id`*.

`ndb_config` can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the `--configinfo` and `--xml` options later in this section).

You can filter the results by section (`DB`, `SYSTEM`, or `CONNECTIONS`) using one of the options `--nodes`, `--system`, or `--connections`.

The following table includes options that are specific to `ndb_config`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_config`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.328 Command-line options for the ndb_config program

Format	Description	Added, Deprecated, or Removed
`--config-file=file_name`	Set the path to config.ini file	All NDB 8.0 releases

Format	Description	Added, Deprecated, or Removed
--config_from_node=#	Obtain configuration data from the node having this ID (must be a data node).	All NDB 8.0 releases
--configinfo	Dumps information about all NDB configuration parameters in text format with default, maximum, and minimum values. Use with --xml to obtain XML output.	All NDB 8.0 releases
--connections	Print connections information ([tcp], [tcp default], [sci], [sci default], [shm], or [shm default] sections of cluster configuration file) only. Cannot be used with --system or --nodes.	All NDB 8.0 releases
--diff-default	Print only configuration parameters that have non-default values	All NDB 8.0 releases
--fields=string, -f	Field separator	All NDB 8.0 releases
--host=name	Specify host	All NDB 8.0 releases
--mycnf	Read configuration data from my.cnf file	All NDB 8.0 releases
--nodeid, --id	Get configuration of node with this ID	All NDB 8.0 releases
--nodes	Print node information ([ndbd] or [ndbd default] section of cluster configuration file) only. Cannot be used with --system or --connections.	All NDB 8.0 releases
-c	Short form for --ndb-connectstring	All NDB 8.0 releases
--query=string, -q	One or more query options (attributes)	All NDB 8.0 releases
--query-all, -a	Dumps all parameters and values to a single comma-delimited string.	All NDB 8.0 releases
--rows=string, -r	Row separator	All NDB 8.0 releases
--system	Print SYSTEM section information only (see ndb_config --configinfo output). Cannot be used with --nodes or --connections.	All NDB 8.0 releases
--type=name	Specify node type	All NDB 8.0 releases
--configinfo --xml	Use --xml with --configinfo to obtain a dump of all NDB configuration parameters in XML	All NDB 8.0 releases

Format	Description	Added, Deprecated, or Removed
	format with default, maximum, and minimum values.	

- `--configinfo`

  The `--configinfo` option causes `ndb_config` to dump a list of each NDB Cluster configuration parameter supported by the NDB Cluster distribution of which `ndb_config` is a part, including the following information:

  - A brief description of each parameter's purpose, effects, and usage
  - The section of the `config.ini` file where the parameter may be used
  - The parameter's data type or unit of measurement
  - Where applicable, the parameter's default, minimum, and maximum values
  - NDB Cluster release version and build information

  By default, this output is in text format. Part of this output is shown here:

```
shell> ndb_config --configinfo

****** SYSTEM ******

Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

****** DB ******

MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

…
```

  Use this option together with the `--xml` option to obtain output in XML format.

- `--config-file=path-to-file`

Property	Value
Command-Line Format	`--config-file=file_name`
Type	File name
Default Value	

  Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--config_from_node=#`

Property	Value
Command-Line Format	`--config-from-node=#`
Type	Numeric
Default Value	`none`
Minimum Value	`1`
Maximum Value	`48`

Obtain the cluster's configuration data from the data node that has this ID.

If the node having this ID is not a data node, `ndb_config` fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

- `--connections`

Property	Value
Command-Line Format	`--connections`
Type	Boolean
Default Value	`FALSE`

Tells `ndb_config` to print `CONNECTIONS` information only—that is, information about parameters found in the `[tcp]`, `[tcp default]`, `[sci]`, `[sci default]`, `[shm]`, or `[shm default]` sections of the cluster configuration file (see Section 22.3.3.10, “NDB Cluster TCP/IP Connections”, Section 22.3.3.13, “SCI Transport Connections in NDB Cluster”, and Section 22.3.3.12, “NDB Cluster Shared-Memory Connections”, for more information).

This option is mutually exclusive with `--nodes` and `--system`; only one of these 3 options can be used.

- `--diff-default`

Property	Value
Command-Line Format	`--diff-default`
Type	Boolean
Default Value	`FALSE`

Print only configuration parameters that have non-default values.

- `--fields=`*`delimiter`*, `-f` *`delimiter`*

Property	Value
Command-Line Format	`--fields=string`
Type	String
Default Value	

Specifies a *`delimiter`* string used to separate the fields in the result. The default is `,` (the comma character).

Note

If the *`delimiter`* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--host=hostname`

Property	Value
Command-Line Format	`--host=name`
Type	String
Default Value	

Specifies the host name of the node for which configuration information is to be obtained.

Note

While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all NDB Cluster configuration values relating to hosts, or verify that all NDB Cluster hosts handle `localhost` in the same fashion.

- `--mycnf`

Property	Value
Command-Line Format	`--mycnf`
Type	Boolean
Default Value	`FALSE`

Read configuration data from the `my.cnf` file.

- `--ndb-connectstring=connection_string`, `-c connection_string`

Property	Value
Command-Line Format	`--ndb-connectstring=connectstring` `--connect-string=connectstring`
Type	String
Default Value	`localhost:1186`

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in Section 22.3.3.3, “NDB Cluster Connection Strings”, and defaults to `localhost:1186`.

- `--nodeid=node_id`

Property	Value
Command-Line Format	`--ndb-nodeid=#`
Type	Numeric
Default Value	`0`

Specify the node ID of the node for which configuration information is to be obtained.

- `--nodes`

Property	Value
Command-Line Format	--nodes
Type	Boolean
Default Value	FALSE

Tells ndb_config to print information relating only to parameters defined in an [ndbd] or [ndbd default] section of the cluster configuration file (see Section 22.3.3.6, "Defining NDB Cluster Data Nodes").

This option is mutually exclusive with --connections and --system; only one of these 3 options can be used.

- --query=*query-options*, -q *query-options*

Property	Value
Command-Line Format	--query=string
Type	String
Default Value	

This is a comma-delimited list of *query options*—that is, a list of one or more node attributes to be returned. These include nodeid (node ID), type (node type—that is, ndbd, mysqld, or ndb_mgmd), and any configuration parameters whose values are to be obtained.

For example, --query=nodeid,type,datamemory,datadir returns the node ID, node type, DataMemory, and DataDir for each node.

Note

If a given parameter is not applicable to a certain type of node, than an empty string is returned for the corresponding value. See the examples later in this section for more information.

- --query-all, -a

Property	Value
Command-Line Format	--query-all
Type	String
Default Value	

Returns a comma-delimited list of all query options (node attributes; note that this list is a single string.

- --rows=*separator*, -r *separator*

Property	Value
Command-Line Format	--rows=string
Type	String
Default Value	

Specifies a *separator* string used to separate the rows in the result. The default is a space character.

Note

If the *`separator`* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--system`

Property	Value
Command-Line Format	`--system`
Type	Boolean
Default Value	`FALSE`

Tells `ndb_config` to print `SYSTEM` information only. This consists of system variables that cannot be changed at run time; thus, there is no corresponding section of the cluster configuration file for them. They can be seen (prefixed with `****** SYSTEM ******`) in the output of `ndb_config --configinfo`.

This option is mutually exclusive with `--nodes` and `--connections`; only one of these 3 options can be used.

- `--type=`*`node_type`*

Property	Value
Command-Line Format	`--type=name`
Type	Enumeration
Default Value	`[none]`

Valid Values	`ndbd`
	`mysqld`
	`ndb_mgmd`

Filters results so that only configuration values applying to nodes of the specified *`node_type`* (`ndbd`, `mysqld`, or `ndb_mgmd`) are returned.

- `--usage`, `--help`, or `-?`

Property	Value
Command-Line Format	`--help` `--usage`

Causes `ndb_config` to print a list of available options, and then exit.

- `--version`, `-V`

Property	Value
Command-Line Format	`--version`

Causes `ndb_config` to print a version information string, and then exit.

- `--configinfo --xml`

Property	Value
Command-Line Format	`--configinfo --xml`

Property	Value
Type	Boolean
Default Value	false

Cause ndb_config --configinfo to provide output as XML by adding this option. A portion of such output is shown in this example:

```
shell> ndb_config --configinfo --xml

<configvariables protocolversion="1" ndbversionstring="5.7.26-ndb-7.5.14"
                    ndbversion="460032" ndbversionmajor="7" ndbversionminor="5"
                    ndbversionbuild="0">

```

Note

Normally, the XML output produced by ndb_config --configinfo --xml is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

The XML output also indicates when changing a given parameter requires that data nodes be restarted using the --initial option. This is shown by the presence of an initial="true" attribute in the corresponding <param> element. In addition, the restart type (system or node) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a restart="system" attribute in the corresponding <param> element. For example, changing the value set for the Diskless parameter requires a system initial restart, as shown here (with the restart and initial attributes highlighted for visibility):

```
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
          restart="system" initial="true"/>
```

Currently, no initial attribute is included in the XML output for <param> elements corresponding to parameters which do not require initial restarts; in other words, initial="false" is the default, and the value false should be assumed if the attribute is not present. Similarly, the default restart

type is node (that is, an online or “rolling” restart of the cluster), but the restart attribute is included only if the restart type is system (meaning that all cluster nodes must be shut down at the same time, then restarted).

Deprecated parameters are indicated in the XML output by the deprecated attribute, as shown here:

```
<param name="NoOfDiskPagesToDiskAfterRestartACC" comment="DiskCheckpointSpeed"
       type="unsigned" default="20" min="1" max="4294967039" deprecated="true"/>
```

In such cases, the comment refers to one or more parameters that supersede the deprecated parameter. Similarly to initial, the deprecated attribute is indicated only when the parameter is deprecated, with deprecated="true", and does not appear at all for parameters which are not deprecated. (Bug #21127135)

Beginning with NDB 7.5.0, parameters that are required are indicated with mandatory="true", as shown here:

```
<param name="NodeId"
         comment="Number identifying application node (mysqld(API))"
         type="unsigned" mandatory="true" min="1" max="255"/>
```

In much the same way that the initial or deprecated attribute is displayed only for a parameter that requires an intial restart or that is deprecated, the mandatory attribute is included only if the given parameter is actually required.

Important

The --xml option can be used only with the --configinfo option. Using --xml without --configinfo fails with an error.

Unlike the options used with this program to obtain current configuration data, --configinfo and --xml use information obtained from the NDB Cluster sources when ndb_config was compiled. For this reason, no connection to a running NDB Cluster or access to a config.ini or my.cnf file is required for these two options.

Combining other ndb_config options (such as --query or --type) with --configinfo (with or without the --xml option is not supported. Currently, if you attempt to do so, the usual result is that all other options besides --configinfo or --xml are simply ignored. *However, this behavior is not guaranteed and is subject to change at any time*. In addition, since ndb_config, when used with the --configinfo option, does not access the NDB Cluster or read any files, trying to specify additional options such as --ndb-connectstring or --config-file with --configinfo serves no purpose.

Examples

1. To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config --query=nodeid,type --fields=':' --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndb_mgmd
6:mysqld
7:mysqld
8:mysqld
9:mysqld
```

In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (`:`), and the `--rows` options to place the values for each node on a new line in the output.

2. To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:

```
shell> ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini \
--query=hostname,portnumber --fields=: --rows=, --type=ndb_mgmd
198.51.100.179:1186
```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, as well as the values set for its `DataMemory` and `DataDir` parameters:

```
shell> ./ndb_config --type=ndbd --query=nodeid,host,datamemory,datadir -f ' : ' -r '\n'
1 : 198.51.100.193 : 83886080 : /usr/local/mysql/cluster-data
2 : 198.51.100.112 : 83886080 : /usr/local/mysql/cluster-data
3 : 198.51.100.176 : 83886080 : /usr/local/mysql/cluster-data
4 : 198.51.100.119 : 83886080 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively, as well as the short option `-q` to pass a list of parameters to to be obtained.

4. To exclude results from any host except one in particular, use the `--host` option:

```
shell> ./ndb_config --host=198.51.100.176 -f : -r '\n' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--nodeid` option.

22.4.8 ndb_delete_all — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given `NDB` table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

Usage

```
ndb_delete_all -c connection_string tbl_name -d db_name
```

This deletes all rows from the table named *`tbl_name`* in the database named *`db_name`*. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

The following table includes options that are specific to `ndb_delete_all`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_delete_all`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.329 Command-line options for the ndb_delete_all program

Format	Description	Added, Deprecated, or Removed
`--database=dbname`, `-d`	Name of the database in which the table is found	All NDB 8.0 releases

Format	Description	Added, Deprecated, or Removed
--transactional, -t	Perform the delete in a single transaction (may run out of operations)	All NDB 8.0 releases
--tupscan	Run tup scan	All NDB 8.0 releases
--diskscan	Run disk scan	All NDB 8.0 releases

- `--transactional`, `-t`

  Use of this option causes the delete operation to be performed as a single transaction.

Warning

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

22.4.9 ndb_desc — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more `NDB` tables.

Usage

```
ndb_desc -c connection_string tbl_name -d db_name [options]

ndb_desc -c connection_string index_name -d db_name -t tbl_name
```

Additional options that can be used with `ndb_desc` are listed later in this section.

Sample Output

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (
    id INT(11) NOT NULL AUTO_INCREMENT,
    name VARCHAR(20) NOT NULL,
    length_mm INT(11) NOT NULL,
    weight_gm INT(11) NOT NULL,

    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
) ENGINE=NDB;

INSERT INTO fish VALUES
    (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
    (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
    (NULL, 'grouper', 900, 125000), (NULL ,'puffer', 250, 2500);
```

Output from `ndb_desc`:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
```

```

uk$unique(name) - UniqueHashIndex
-- Per partition info --
Partition       Row count       Commit count    Frag fixed memory       Frag varsized memory    Extent_spac
0               2               2               32768                   32768                   0
1               4               4               32768                   32768                   0

NDBT_ProgramExit: 0 - OK
```

Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

You can obtain additional information about a specific index using the `--table` (short form: `-t`) option and supplying the name of the index as the first argument to `ndb_desc`, as shown here:

```
shell> ./ndb_desc uk -d test -t fish
-- uk --
Version: 2
Base table: fish
Number of attributes: 1
Logging: 0
Index type: OrderedIndex
Index status: Retrieved
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
-- IndexTable 10/uk --
Version: 2
Fragment type: FragUndefined
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: yes
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 0
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 2
ForceVarPart: 0
PartitionCount: 2
FragmentCount: 2
FragmentCountType: ONE_PER_LDM_PER_NODE
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
```

```
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
NDB$TNODE Unsigned [64] PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY(NDB$TNODE) - UniqueHashIndex

NDBT_ProgramExit: 0 - OK
```

When an index is specified in this way, the `--extra-partition-info` and `--extra-node-info` options have no effect.

The `Version` column in the output contains the table's schema object version. For information about interpreting this value, see NDB Schema Object Versions.

Three of the table properties that can be set using `NDB_TABLE` comments embedded in `CREATE TABLE` and `ALTER TABLE` statements are also visible in `ndb_desc` output. The table's `FRAGMENT_COUNT_TYPE` is always shown in the `FragmentCountType` column. `READ_ONLY` and `FULLY_REPLICATED`, if set to 1, are shown in the `Table options` column. You can see this after executing the following `ALTER TABLE` statement in the `mysql` client:

```
mysql> ALTER TABLE fish COMMENT='NDB_TABLE=READ_ONLY=1,FULLY_REPLICATED=1';
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
+---------+------+-----------------------------------------------------------------------------------------------
| Level   | Code | Message
+---------+------+-----------------------------------------------------------------------------------------------
| Warning | 1296 | Got error 4503 'Table property is FRAGMENT_COUNT_TYPE=ONE_PER_LDM_PER_NODE but not i
+---------+------+-----------------------------------------------------------------------------------------------
1 row in set (0.00 sec)
```

The warning is issued because `READ_ONLY=1` requires that the table's fragment count type is (or be set to) `ONE_PER_LDM_PER_NODE_GROUP`; `NDB` sets this automatically in such cases. You can check that the `ALTER TABLE` statement has the desired effect using `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE fish\G
*************************** 1. row ***************************
       Table: fish
Create Table: CREATE TABLE `fish` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `name` varchar(20) NOT NULL,
  `length_mm` int(11) NOT NULL,
  `weight_gm` int(11) NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `uk` (`name`)
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
COMMENT='NDB_TABLE=READ_BACKUP=1,FULLY_REPLICATED=1'
1 row in set (0.01 sec)
```

Because `FRAGMENT_COUNT_TYPE` was not set explicitly, its value is not shown in the comment text printed by `SHOW CREATE TABLE`. `ndb_desc`, however, displays the updated value for this attribute. The `Table options` column shows the binary properties just enabled. You can see this in the output shown here (emphasized text):

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 4
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 380
```

```
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 1
FragmentCount: 1
FragmentCountType: ONE_PER_LDM_PER_NODE_GROUP
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options: readbackup, fullyreplicated
HashMap: DEFAULT-HASHMAP-3840-1
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY DYNAMIC
length_mm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
weight_gm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk(name) - OrderedIndex
uk$unique(name) - UniqueHashIndex
-- Per partition info --
Partition       Row count       Commit count    Frag fixed memory       Frag varsized memory    Extent_spac

NDBT_ProgramExit: 0 - OK
```

For more information about these table properties, see Section 13.1.20.11, “Setting NDB_TABLE Options”.

The `Extent_space` and `Free extent_space` columns are applicable only to `NDB` tables having columns on disk; for tables having only in-memory columns, these columns always contain the value `0`.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```
CREATE LOGFILE GROUP lg_1
    ADD UNDOFILE 'undo_1.log'
    INITIAL_SIZE 16M
    UNDO_BUFFER_SIZE 2M
    ENGINE NDB;

ALTER LOGFILE GROUP lg_1
    ADD UNDOFILE 'undo_2.log'
    INITIAL_SIZE 12M
    ENGINE NDB;

CREATE TABLESPACE ts_1
    ADD DATAFILE 'data_1.dat'
    USE LOGFILE GROUP lg_1
    INITIAL_SIZE 32M
    ENGINE NDB;

ALTER TABLESPACE ts_1
    ADD DATAFILE 'data_2.dat'
    INITIAL_SIZE 48M
    ENGINE NDB;
```

(For more information on the statements just shown and the objects created by them, see Section 22.5.13.1, “NDB Cluster Disk Data Objects”, as well as Section 13.1.16, “CREATE LOGFILE GROUP Syntax”, and Section 13.1.21, “CREATE TABLESPACE Syntax”.)

Now we can create and populate a version of the `fish` table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

```
CREATE TABLE fish (
    id INT(11) NOT NULL AUTO_INCREMENT,
```

```
    name VARCHAR(20) NOT NULL,
    length_mm INT(11) NOT NULL,
    weight_gm INT(11) NOT NULL,

    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE=NDB;

INSERT INTO fish VALUES
    (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
    (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
    (NULL, 'grouper', 900, 125000), (NULL ,'puffer', 250, 2500);
```

When run against this version of the table, ndb_desc displays the following output:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 1
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 346
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 2
FragmentCount: 2
FragmentCountType: ONE_PER_LDM_PER_NODE
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options:
HashMap: DEFAULT-HASHMAP-3840-2
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=DISK
weight_gm Int NOT NULL AT=FIXED ST=DISK
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk(name) - OrderedIndex
uk$unique(name) - UniqueHashIndex
-- Per partition info --
Partition       Row count       Commit count    Frag fixed memory       Frag varsized memory    Extent_
0               2               2               32768                   32768                   1048576
1               4               4               32768                   32768                   1048576

NDBT_ProgramExit: 0 - OK
```

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words, 1048576 - 1044440 = 4136 bytes per partition is currently being used to store the data from this table's disk-based columns. The number of bytes shown as `Free extent_space` is available for storing on-disk column data from the `fish` table only; for this reason, it is not visible when selecting from the `INFORMATION_SCHEMA.FILES` table.

For fully replicated tables, ndb_desc shows only the nodes holding primary partition fragment replicas; nodes with copy fragment replicas (only) are ignored. Beginning with NDB 7.5.4, you can obtain such information, using the mysql client, from the `table_distribution_status`, `table_fragments`, `table_info`, and `table_replicas` tables in the `ndbinfo` database.

The following table includes options that are specific to ndb_desc. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_desc), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.330 Command-line options for the ndb_desc program

Format	Description	Added, Deprecated, or Removed
--blob-info, -b	Include partition information for BLOB tables in output. Requires that the -p option also be used	All NDB 8.0 releases
--database=dbname, -d	Name of database containing table	All NDB 8.0 releases
--extra-node-info, -n	Include partition-to-data-node mappings in output. Requires that the -p option also be used	All NDB 8.0 releases
--extra-partition-info, -p	Display information about partitions	All NDB 8.0 releases
--retries=#, -r	Number of times to retry the connection (once per second)	All NDB 8.0 releases
--table=tbl_name, -t	Specify the table in which to find an index. When this option is used, -p and -n have no effect and are ignored.	All NDB 8.0 releases
--unqualified, -u	Use unqualified table names	All NDB 8.0 releases

- `--blob-info`, `-b`

  Include information about subordinate `BLOB` and `TEXT` columns.

  Use of this option also requires the use of the `--extra-partition-info` (`-p`) option.

- `--database=db_name`, `-d`

  Specify the database in which the table should be found.

- `--extra-node-info`, `-n`

  Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in NDB Cluster.

  Use of this option also requires the use of the `--extra-partition-info` (`-p`) option.

- `--extra-partition-info`, `-p`

  Print additional information about the table's partitions.

- `--retries=#`, `-r`

  Try to connect this many times before giving up. One connect attempt is made per second.

- `--table=tbl_name`, `-t`

  Specify the table in which to look for an index.

- `--unqualified`, `-u`

  Use unqualified table names.

In NDB 7.5.3 and later, table indexes listed in the output are ordered by ID. Previously, this was not deterministic and could vary between platforms. (Bug #81763, Bug #23547742)

22.4.10 ndb_drop_index — Drop Index from an NDB Table

`ndb_drop_index` drops the specified index from an `NDB` table. *It is recommended that you use this utility only as an example for writing NDB API applications*—see the Warning later in this section for details.

Usage

```
ndb_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named *`index`* from the *`table`* in the *`database`*.

The following table includes options that are specific to `ndb_drop_index`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_drop_index`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.331 Command-line options for the ndb_drop_index program

Format	Description	Added, Deprecated, or Removed
`--database=dbname`, `-d`	Name of the database in which the table is found	All NDB 8.0 releases

Warning

Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```
shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK

NDBT_ProgramExit: 0 - OK

shell> ./mysql -u jon -p ctest1
Enter password: *******
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.7.26-ndb-7.5.14

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW TABLES;
+------------------+
| Tables_in_ctest1 |
+------------------+
| a                |
| bt1              |
| bt2              |
| dogs             |
| employees        |
| fish             |
+------------------+
```

```
6 rows in set (0.00 sec)

mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): Got error 4243 'Index not found' from NDBCLUSTER
```

In such a case, your *only* option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statementDROP TABLE or the ndb_drop_table utility (see Section 22.4.11, “ndb_drop_table — Drop an NDB Table”) to drop the table.

22.4.11 ndb_drop_table — Drop an NDB Table

ndb_drop_table drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, the attempt fails with the error 723: No such table exists.) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL DROP TABLE statement on an NDB table.

Usage

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

The following table includes options that are specific to ndb_drop_table. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_drop_table), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.332 Command-line options for the ndb_drop_table program

Format	Description	Added, Deprecated, or Removed
--database=dbname, -d	Name of the database in which the table is found	All NDB 8.0 releases

Prior to NDB 8.0.17, an NDB table dropped using this utility persisted in the MySQL data dictionary but could not be dropped using DROP TABLE in the mysql client. In NDB 8.0.17 and later, such “orphan” tables can be dropped using DROP TABLE. (Bug #29125206, Bug #93672)

22.4.12 ndb_error_reporter — NDB Error-Reporting Utility

ndb_error_reporter creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in NDB Cluster*.

The following table includes command options specific to the NDB Cluster program ndb_error_reporter. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_error_reporter), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.333 Command-line options for the ndb_error_reporter program

Format	Description	Added, Deprecated, or Removed
--connection-timeout=timeout	Number of seconds to wait when connecting to nodes before timing out.	All NDB 8.0 releases
--dry-scp	Disable scp with remote hosts; used only for testing.	All NDB 8.0 releases
--fs	Include file system data in error report; can use a large amount of disk space	All NDB 8.0 releases

Format	Description	Added, Deprecated, or Removed
--skip-nodegroup=nodegroup_id	Skip all nodes in the node group having this ID.	All NDB 8.0 releases

Usage

```
ndb_error_reporter path/to/config-file [username] [options]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (usually named config.ini). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. ndb_error_reporter then includes all of these files in archive that is created in the same directory in which it is run. The archive is named ndb_error_report_*YYYYMMDDHHMMSS*.tar.bz2, where *YYYYMMDDHHMMSS* is a datetime string.

ndb_error_reporter also accepts the options listed here:

- --connection-timeout=*timeout*

Property	Value
Command-Line Format	--connection-timeout=timeout
Type	Integer
Default Value	0

Wait this many seconds when trying to connect to nodes before timing out.

- --dry-scp

Property	Value
Command-Line Format	--dry-scp
Type	Boolean
Default Value	TRUE

Run ndb_error_reporter without using scp from remote hosts. Used for testing only.

- --fs

Property	Value
Command-Line Format	--fs
Type	Boolean
Default Value	FALSE

Copy the data node file systems to the management host and include them in the archive.

Because data node file systems can be extremely large, even after being compressed, we ask that you please do *not* send archives created using this option to Oracle unless you are specifically requested to do so.

- --skip-nodegroup=*nodegroup_id*

Property	Value
Command-Line Format	--connection-timeout=timeout
Type	Integer

Property	Value
Default Value	0

Skip all nodes belong to the node group having the supplied node group ID.

22.4.13 ndb_import — Import CSV Data Into NDB

ndb_import imports CSV-formatted data, such as that produced by mysqldump --tab, directly into NDB using the NDB API. ndb_import requires a connection to an NDB management server (ndb_mgmd) to function; it does not require a connection to a MySQL Server.

Usage

```
ndb_import db_name file_name options
```

ndb_import requires two arguments. *db_name* is the name of the database where the table into which to import the data is found; *file_name* is the name of the CSV file from which to read the data; this must include the path to this file if it is not in the current directory. The name of the file must match that of the table; the file's extension, if any, is not taken into consideration. Options supported by ndb_import include those for specifying field separators, escapes, and line terminators, and are described later in this section. ndb_import must be able to connect to an NDB Cluster management server; for this reason, there must be an unused [api] slot in the cluster config.ini file.

To duplicate an existing table that uses a different storage engine, such as InnoDB, as an NDB table, use the mysql client to perform a SELECT INTO OUTFILE statement to export the existing table to a CSV file, then to execute a CREATE TABLE LIKE statement to create a new table having the same structure as the existing table, then perform ALTER TABLE ... ENGINE=NDB on the new table; after this, from the system shell, invoke ndb_import to load the data into the new NDB table. For example, an existing InnoDB table named myinnodb_table in a database named myinnodb can be exported into an NDB table named myndb_table in a database named myndb as shown here, assuming that you are already logged in as a MySQL user with the appropriate privileges:

1. In the mysql client:

```
mysql> USE myinnodb;

mysql> SELECT * INTO OUTFILE '/tmp/myndb_table.csv'
     >  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\\'
     >  LINES TERMINATED BY '\n'
     >  FROM myinnodbtable;

mysql> CREATE DATABASE myndb;

mysql> USE myndb;

mysql> CREATE TABLE myndb_table LIKE myinnodb.myinnodb_table;

mysql> ALTER TABLE myndb_table ENGINE=NDB;

mysql> EXIT;
Bye
shell>
```

   Once the target database and table have been created, a running mysqld is no longer required. You can stop it using mysqladmin shutdown or another method before proceeding, if you wish.

2. In the system shell:

```
# if you are not already in the MySQL bin directory:
shell> cd path-to-mysql-bin-dir
```

```
shell> ndb_import myndb /tmp/myndb_table.csv --fields-optionally-enclosed-by='"' \
    --fields-terminated-by="," --fields-escaped-by='\\'
```

The output should resemble what is shown here:

```
job-1 import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [running] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 [success] import myndb.myndb_table from /tmp/myndb_table.csv
job-1 imported 19984 rows in 0h0m9s at 2277 rows/s
jobs summary: defined: 1 run: 1 with success: 1 with failure: 0
shell>
```

The following table includes options that are specific to ndb_import. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_import), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.334 Command-line options for the ndb_import program

Format	Description	Added, Deprecated, or Removed
--abort-on-error	Dump core on any fatal error; used for debugging	All NDB 8.0 releases
--ai-increment=#	For table with hidden PK, specify autoincrement increment. See mysqld	All NDB 8.0 releases
--ai-offset=#	For table with hidden PK, specify autoincrement offset. See mysqld	All NDB 8.0 releases
--ai-prefetch-sz=#	For table with hidden PK, specify number of autoincrement values that are prefetched. See mysqld	All NDB 8.0 releases
--connections=#	Number of cluster connections to create	All NDB 8.0 releases
--continue	When job fails, continue to next job	All NDB 8.0 releases
--db-workers=#	Number of threads, per data node, executing database operations	All NDB 8.0 releases
--errins-type=name	Error insert type, for testing purposes; use "list" to obtain all possible values	All NDB 8.0 releases
--errins-delay=#	Error insert delay in milliseconds; random variation is added	All NDB 8.0 releases
--fields-enclosed-by=char	Same as FIELDS ENCLOSED BY option for LOAD DATA statements. For CSV input this is same as using --fields-optionally-enclosed-by	All NDB 8.0 releases
--fields-escaped-by=name	Same as FIELDS ESCAPED BY option for LOAD DATA statements	All NDB 8.0 releases
--fields-optionally-enclosed-by=char	Same as FIELDS OPTIONALLY ENCLOSED BY option for LOAD DATA statements	All NDB 8.0 releases

Format	Description	Added, Deprecated, or Removed
--fields-terminated-by=char	Same as FIELDS TERMINATED BY option for LOAD DATA statements.	All NDB 8.0 releases
--idlesleep=#	Number of milliseconds to sleep waiting for more to do	All NDB 8.0 releases
--idlespin=#	Number of times to re-try before idlesleep	All NDB 8.0 releases
--ignore-lines=#	Ignore first # lines in input file. Used to skip a non-data header.	All NDB 8.0 releases
--input-type=name	Input type: random or csv	All NDB 8.0 releases
--input-workers=#	Number of threads processing input. Must be 2 or more if --input-type is csv.	All NDB 8.0 releases
--keep-state	Preserve state files	All NDB 8.0 releases
--lines-terminated-by=name	Same as LINES TERMINATED BY option for LOAD DATA statements	All NDB 8.0 releases
--log-level=#	Set internal logging level; for debugging and development	All NDB 8.0 releases
--max-rows=#	Import only this number of input data rows; default is 0, which imports all rows	All NDB 8.0 releases
--monitor=#	Periodically print status of running job if something has changed (status, rejected rows, temporary errors). Value 0 disables. Value 1 prints any change seen. Higher values reduce status printing exponentially up to some pre-defined limit.	All NDB 8.0 releases
--no-asynch	Run database operations as batches, in single transactions	All NDB 8.0 releases
--no-hint	Do not use distribution key hint to select data node (TC)	All NDB 8.0 releases
--opbatch=#	A db execution batch is a set of transactions and operations sent to NDB kernel. This option limits NDB operations (including blob operations) in a db execution batch. Therefore it also limits number of asynch transactions. Value 0 is not valid	All NDB 8.0 releases
--opbytes=#	Limit bytes in execution batch (default 0 = no limit)	All NDB 8.0 releases
--output-type=name	Output type: ndb is default, null used for testing	All NDB 8.0 releases
--output-workers=#	Number of threads processing output or relaying database operations	All NDB 8.0 releases

Format	Description	Added, Deprecated, or Removed
--pagesize=#	Align I/O buffers to given size	All NDB 8.0 releases
--pagecnt=#	Size of I/O buffers as multiple of page size. CSV input worker allocates a double-sized buffer	All NDB 8.0 releases
--polltimeout=#	Timeout per poll for completed asynchonous transactions; polling continues until all polls are completed, or error occurs	All NDB 8.0 releases
--rejects=#	Limit number of rejected rows (rows with permanent error) in data load. Default is 0 which means that any rejected row causes a fatal error. The row exceeding the limit is also added to *.rej	All NDB 8.0 releases
--resume	If job aborted (temporary error, user interrupt), resume with rows not yet processed	All NDB 8.0 releases
--rowbatch=#	Limit rows in row queues (default 0 = no limit); must be 1 or more if --input-type is random	All NDB 8.0 releases
--rowbytes=#	Limit bytes in row queues (0 = no limit)	All NDB 8.0 releases
--state-dir=name	Where to write state files; currect directory is default	All NDB 8.0 releases
--stats	Save performance and statistics information in *.sto and *.stt files	All NDB 8.0 releases
--tempdelay=#	Number of milliseconds to sleep between temporary errors	All NDB 8.0 releases
--temperrors=#	Number of times a transaction can fail due to a temporary error, per execution batch; 0 means any temporary error is fatal. Such errors do not cause any rows to be written to .rej file	All NDB 8.0 releases
--verbose=#, -v	Enable verbose output	All NDB 8.0 releases

- --abort-on-error

Property	Value
Command-Line Format	--abort-on-error
Type	Boolean
Default Value	FALSE

Dump core on any fatal error; used for debugging only.

- --ai-increment=#

Property	Value
Command-Line Format	--ai-increment=#
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	4294967295

For a table with a hidden primary key, specify the autoincrement increment, like the the auto_increment_increment system variable does in the MySQL Server.

- --ai-offset=#

Property	Value
Command-Line Format	--ai-offset=#
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	4294967295

For a table with hidden primary key, specify the autoincrement offset. Similar to the auto_increment_offset system variable.

- --ai-prefetch-sz=#

Property	Value
Command-Line Format	--ai-prefetch-sz=#
Type	Integer
Default Value	1024
Minimum Value	1
Maximum Value	4294967295

For a table with a hidden primary key, specify the number of autoincrement values that are prefetched. Behaves like the ndb_autoincrement_prefetch_sz system variable does in the MySQL Server.

- --connections=#

Property	Value
Command-Line Format	--connections=#
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	4294967295

Number of cluster connections to create.

- --continue

Property	Value
Command-Line Format	--continue

Property	Value
Type	Boolean
Default Value	FALSE

When a job fails, continue to the next job.

- --db-workers=#

Property	Value
Command-Line Format	--db-workers=#
Type	Integer
Default Value	4
Minimum Value	1
Maximum Value	4294967295

Number of threads, per data node, executing database operations.

- --errins-type=*name*

Property	Value
Command-Line Format	--errins-type=name
Type	Enumeration
Default Value	[none]
Valid Values	stopjob stopall sighup sigint list

Error insert type; use list as the *name* value to obtain all possible values. This option is used for testing purposes only.

- --errins-delay=#

Property	Value
Command-Line Format	--errins-delay=#
Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	4294967295

Error insert delay in milliseconds; random variation is added. This option is used for testing purposes only.

- --fields-enclosed-by=*char*

Property	Value
Command-Line Format	--fields-enclosed-by=char

Property	Value
Type	String
Default Value	[none]

This works in the same way as the FIELDS ENCLOSED BY option does for the LOAD DATA statement, specifying a character to be interpeted as quoting field values. For CSV input, this is the same as --fields-optionally-enclosed-by.

- --fields-escaped-by=*name*

Property	Value
Command-Line Format	--fields-escaped-by=name
Type	String
Default Value	\

Specify an escape character in the same way as the FIELDS ESCAPED BY option does for the SQL LOAD DATA statement.

- --fields-optionally-enclosed-by=*char*

Property	Value
Command-Line Format	--fields-optionally-enclosed-by=char
Type	String
Default Value	[none]

This works in the same way as the FIELDS OPTIONALLY ENCLOSED BY option does for the LOAD DATA statement, specifying a character to be interpeted as optionally quoting field values. For CSV input, this is the same as --fields-enclosed-by.

- --fields-terminated-by=*char*

Property	Value
Command-Line Format	--fields-terminated-by=char
Type	String
Default Value	\t

This works in the same way as the FIELDS TERMINATED BY option does for the LOAD DATA statement, specifying a character to be interpeted as the field separator.

- --idlesleep=#

Property	Value
Command-Line Format	--idlesleep=#
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	4294967295

Number of milliseconds to sleep waiting for more work to perform.

- --idlespin=#

Property	Value
Command-Line Format	`--idlespin=#`
Type	Integer
Default Value	`0`
Minimum Value	`0`
Maximum Value	`4294967295`

Number of times to retry before sleeping.

- `--ignore-lines=#`

Property	Value
Command-Line Format	`--ignore-lines=#`
Type	Integer
Default Value	`0`
Minimum Value	`0`
Maximum Value	`4294967295`

Cause ndb_import to ignore the first `#` lines of the input file. This can be employed to skip a file header that does not contain any data.

- `--input-type=name`

Property	Value
Command-Line Format	`--input-type=name`
Type	Enumeration
Default Value	`csv`
Valid Values	`random` `csv`

Set the type of input type. The default is `csv`; `random` is intended for testing purposes only. .

- `--input-workers=#`

Property	Value
Command-Line Format	`--input-workers=#`
Type	Integer
Default Value	`4`
Minimum Value	`1`
Maximum Value	`4294967295`

Set the number of threads processing input.

- `--keep-state`

Property	Value
Command-Line Format	`--keep-state`
Type	Boolean
Default Value	`false`

By default, ndb_import removes all state files (except non-empty `*.rej` files) when it completes a job. Specify this option (nor argument is required) to force the program to retain all state files instead.

- `--lines-terminated-by=`*`name`*

Property	Value
Command-Line Format	`--lines-terminated-by=name`
Type	String
Default Value	`\n`

This works in the same way as the `LINES TERMINATED BY` option does for the `LOAD DATA` statement, specifying a character to be interpeted as end-of-line.

- `--log-level=#`

Property	Value
Command-Line Format	`--log-level=#`
Type	Integer
Default Value	`0`
Minimum Value	`0`
Maximum Value	`2`

Performs internal logging at the given level. This option is intended primarily for internal and development use.

In debug builds of NDB only, the logging level can be set using this option to a maximum of 4.

- `--max-rows=#`

Property	Value
Command-Line Format	`--max-rows=#`
Type	Integer
Default Value	`0`
Minimum Value	`0`
Maximum Value	`4294967295`

Import only this number of input data rows; the default is 0, which imports all rows.

- `--monitor=#`

Property	Value
Command-Line Format	`--monitor=#`
Type	Integer
Default Value	`2`
Minimum Value	`0`
Maximum Value	`4294967295`

Periodically print the status of a running job if something has changed (status, rejected rows, temporary errors). Set to 0 to disable this reporting. Setting to 1 prints any change that is seen. Higher values reduce the frequency of this status reporting.

- `--no-asynch`

Property	Value
Command-Line Format	--no-asynch
Type	Boolean
Default Value	FALSE

Run database operations as batches, in single transactions.

- --no-hint

Property	Value
Command-Line Format	--no-hint
Type	Boolean
Default Value	FALSE

Do not use distribution key hinting to select a data node.

- --opbatch=#

Property	Value
Command-Line Format	--opbatch=#
Type	Integer
Default Value	256
Minimum Value	1
Maximum Value	4294967295

Set a limit on the number of operations (including blob operations), and thus the number of asynchronous transactions, per execution batch.

- --opbytes=#

Property	Value
Command-Line Format	--opbytes=#
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

Set a limit on the number of bytes per execution batch. Use 0 for no limit.

- --output-type=*name*

Property	Value
Command-Line Format	--output-type=name
Type	Enumeration
Default Value	ndb
Valid Values	null

Set the output type. ndb is the default. null is used only for testing.

- --output-workers=#

Property	Value
Command-Line Format	`--output-workers=#`
Type	Integer
Default Value	`2`
Minimum Value	`1`
Maximum Value	`4294967295`

Set the number of threads processing output or relaying database operations.

- `--pagesize=#`

Property	Value
Command-Line Format	`--pagesize=#`
Type	Integer
Default Value	`4096`
Minimum Value	`1`
Maximum Value	`4294967295`

Align I/O buffers to the given size.

- `--pagecnt=#`

Property	Value
Command-Line Format	`--pagecnt=#`
Type	Integer
Default Value	`64`
Minimum Value	`1`
Maximum Value	`4294967295`

Set the size of I/O buffers as multiple of page size. The CSV input worker allocates buffer that is doubled in size.

- `--polltimeout=#`

Property	Value
Command-Line Format	`--polltimeout=#`
Type	Integer
Default Value	`1000`
Minimum Value	`1`
Maximum Value	`4294967295`

Set a timeout per poll for completed asynchonous transactions; polling continues until all polls are completed, or until an error occurs.

- `--rejects=#`

Property	Value
Command-Line Format	`--rejects=#`
Type	Integer

Property	Value
Default Value	0
Minimum Value	0
Maximum Value	4294967295

Limit the number of rejected rows (rows with permanent errors) in the data load. The default is 0, which means that any rejected row causes a fatal error. Any rows causing the limit to be exceeded are added to the .rej file.

The limit imposed by this option is effective for the duration of the current run. A run restarted using --resume is considered a “new” run for this purpose.

- --resume

Property	Value
Command-Line Format	--resume
Type	Boolean
Default Value	FALSE

If a job is aborted (due to a temporary db error or when interrupted by the user), resume with any rows not yet processed.

- --rowbatch=#

Property	Value
Command-Line Format	--rowbatch=#
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

Set a limit on the number of rows per row queue. Use 0 for no limit.

- --rowbytes=#

Property	Value
Command-Line Format	--rowbytes=#
Type	Integer
Default Value	262144
Minimum Value	0
Maximum Value	4294967295

Set a limit on the number of bytes per row queue. Use 0 for no limit.

- --stats

Property	Value
Command-Line Format	--stats
Type	Boolean
Default Value	false

Save information about options related to performance and other internal statistics in files named *.sto and *.stt. These files are always kept on successful completion (even if --keep-state is not also specified).

- --state-dir=*name*

Property	Value
Command-Line Format	--state-dir=name
Type	String
Default Value	.

Where to write the state files (*tbl_name*.map, *tbl_name*.rej, *tbl_name*.res, and *tbl_name*.stt) produced by a run of the program; the default is the current directory.

- --tempdelay=#

Property	Value
Command-Line Format	--tempdelay=#
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	4294967295

Number of milliseconds to sleep between temporary errors.

- --temperrors=#

Property	Value
Command-Line Format	--temperrors=#
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

Number of times a transaction can fail due to a temporary error, per execution batch. The default is 0, which means that any temporary error is fatal. Temporary errors do not cause any rows to be added to the .rej file.

- --verbose, -v

Property	Value
Command-Line Format	--verbose
Type	Boolean
Default Value	false

Enable verbose output.

As with LOAD DATA, options for field and line formatting much match those used to create the CSV file, whether this was done using SELECT INTO ... OUTFILE, or by some other means. There is no equivalent to the LOAD DATA statement STARTING WITH option.

ndb_import was added in NDB 7.6.2.

22.4.14 ndb_index_stat — NDB Index Statistics Utility

ndb_index_stat provides per-fragment statistical information about indexes on NDB tables. This includes cache version and age, number of index entries per partition, and memory consumption by indexes.

Usage

To obtain basic index statistics about a given NDB table, invoke ndb_index_stat as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the --database (-d) option:

```
ndb_index_stat table -d database
```

In this example, we use ndb_index_stat to obtain such information about an NDB table named mytable in the test database:

```
shell> ndb_index_stat -d test mytable
table:City index:PRIMARY fragCount:2
sampleVersion:3 loadTime:1399585986 sampleCount:1994 keyBytes:7976
query cache: valid:1 sampleCount:1994 totalBytes:27916
times in ms: save: 7.133 sort: 1.974 sort per sample: 0.000

NDBT_ProgramExit: 0 - OK
```

sampleVersion is the version number of the cache from which the statistics data is taken. Running ndb_index_stat with the --update option causes sampleVersion to be incremented.

loadTime shows when the cache was last updated. This is expressed as seconds since the Unix Epoch.

sampleCount is the number of index entries found per partition. You can estimate the total number of entries by multiplying this by the number of fragments (shown as fragCount).

sampleCount can be compared with the cardinality of SHOW INDEX or INFORMATION_SCHEMA.STATISTICS, although the latter two provide a view of the table as a whole, while ndb_index_stat provides a per-fragment average.

keyBytes is the number of bytes used by the index. In this example, the primary key is an integer, which requires four bytes for each index, so keyBytes can be calculated in this case as shown here:

```
    keyBytes = sampleCount * (4 bytes per index) = 1994 * 4 = 7976
```

This information can also be obtained using the corresponding column definitions from INFORMATION_SCHEMA.COLUMNS (this requires a MySQL Server and a MySQL client application).

totalBytes is the total memory consumed by all indexes on the table, in bytes.

Timings shown in the preceding examples are specific to each invocation of ndb_index_stat.

The --verbose option provides some additional output, as shown here:

```
shell> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache created
```

```
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
disconnected

NDBT_ProgramExit: 0 - OK

shell>
```

If the only output from the program is `NDBT_ProgramExit: 0 - OK`, this may indicate that no statistics yet exist. To force them to be created (or updated if they already exist), invoke `ndb_index_stat` with the `--update` option, or execute `ANALYZE TABLE` on the table in the `mysql` client.

Options

The following table includes options that are specific to the NDB Cluster `ndb_index_stat` utility. Additional descriptions are listed following the table. For options common to most NDB Cluster programs (including `ndb_index_stat`), see Section 22.4.31, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

Table 22.335 Command-line options for the ndb_index_stat program

Format	Description	Added, Deprecated, or Removed
`--database=name`, `-d`	Name of the database containing the table.	All NDB 8.0 releases
`--delete`	Delete index statistics for the given table, stopping any auto-update previously configured.	All NDB 8.0 releases
`--update`	Update index statistics for the given table, restarting any auto-update previously configured.	All NDB 8.0 releases
`--dump`	Print the query cache.	All NDB 8.0 releases
`--query=#`	Perform a number of random range queries on first key attr (must be int unsigned).	All NDB 8.0 releases
`--sys-drop`	Drop any statistics tables and events in NDB kernel (all statistics are lost)	All NDB 8.0 releases
`--sys-create`	Create all statistics tables and events in NDB kernel, if none of them already exist	All NDB 8.0 releases
`--sys-create-if-not-exist`	Create any statistics tables and events in NDB kernel that do not already exist.	All NDB 8.0 releases
`--sys-create-if-not-valid`	Create any statistics tables or events that do not already exist in the NDB kernel. after dropping any that are invalid.	All NDB 8.0 releases
`--sys-check`	Verify that NDB system index statistics and event tables exist.	All NDB 8.0 releases
`--sys-skip-tables`	Do not apply sys-* options to tables.	All NDB 8.0 releases
`--sys-skip-events`	Do not apply sys-* options to events.	All NDB 8.0 releases

Format	Description	Added, Deprecated, or Removed
`--verbose`, `-v`	Turn on verbose output	All NDB 8.0 releases
`--loops=#`	Set the number of times to perform a given command. Default is 0.	All NDB 8.0 releases

ndb_index_stat statistics options. The following options are used to generate index statistics. They work with a given table and database. They cannot be mixed with system options (see ndb_index_stat system options).

- `--database=name`, `-d name`

Property	Value
Command-Line Format	`--database=name`
Type	String
Default Value	`[none]`
Minimum Value	
Maximum Value	

The name of the database that contains the table being queried.

- `--delete`

Property	Value
Command-Line Format	`--delete`
Type	Boolean
Default Value	`false`
Minimum Value	
Maximum Value	

Delete the index statistics for the given table, stopping any auto-update that was previously configured.

- `--update`

Property	Value
Command-Line Format	`--update`
Type	Boolean
Default Value	`false`
Minimum Value	
Maximum Value	

Update the index statistics for the given table, and restart any auto-update that was previously configured.

- `--dump`

Property	Value
Command-Line Format	`--dump`

Property	Value
Type	Boolean
Default Value	`false`
Minimum Value	
Maximum Value	

Dump the contents of the query cache.

- `--query=#`

Property	Value
Command-Line Format	`--query=#`
Type	Numeric
Default Value	`0`
Minimum Value	`0`
Maximum Value	`MAX_INT`

Perform random range queries on first key attribute (must be int unsigned).

ndb_index_stat system options. The following options are used to generate and update the statistics tables in the NDB kernel. None of these options can be mixed with statistics options (see ndb_index_stat statistics options).

- `--sys-drop`

Property	Value
Command-Line Format	`--sys-drop`
Type	Boolean
Default Value	`false`
Minimum Value	
Maximum Value	

Drop all statistics tables and events in the NDB kernel. *This causes all statistics to be lost*.

- `--sys-create`

Property	Value
Command-Line Format	`--sys-create`
Type	Boolean
Default Value	`false`
Minimum Value	
Maximum Value	

Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

- `sys-create-if-not-exist`

Property	Value
Command-Line Format	`--sys-create-if-not-exist`
Type	Boolean

Property	Value
Default Value	false
Minimum Value	
Maximum Value	

Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

- --sys-create-if-not-valid

Property	Value
Command-Line Format	--sys-create-if-not-valid
Type	Boolean
Default Value	false
Minimum Value	
Maximum Value	

Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

- --sys-check

Property	Value
Command-Line Format	--sys-check
Type	Boolean
Default Value	false
Minimum Value	
Maximum Value	

Verify that all required system statistics tables and events exist in the NDB kernel.

- --sys-skip-tables

Property	Value
Command-Line Format	--sys-skip-tables
Type	Boolean
Default Value	false
Minimum Value	
Maximum Value	

Do not apply any --sys-* options to any statistics tables.

- --sys-skip-events

Property	Value
Command-Line Format	--sys-skip-events
Type	Boolean
Default Value	false
Minimum Value	
Maximum Value	

Do not apply any `--sys-*` options to any events.

- `--verbose`

Property	Value
Command-Line Format	`--verbose`
Type	Boolean
Default Value	`false`
Minimum Value	
Maximum Value	

Turn on verbose output.

- `--loops=#`

Property	Value
Command-Line Format	`--loops=#`
Type	Numeric
Default Value	`0`
Minimum Value	`0`
Maximum Value	`MAX_INT`

Repeat commands this number of times (for use in testing).

22.4.15 ndb_move_data — NDB Data Copy Utility

`ndb_move_data` copies data from one NDB table to another.

Usage

The program is invoked with the names of the source and target tables; either or both of these may be qualified optionally with the database name. Both tables must use the NDB storage engine.

```
ndb_move_data options source target
```

The following table includes options that are specific to `ndb_move_data`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_move_data`), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.336 Command-line options for the ndb_move_data program

Format	Description	Added, Deprecated, or Removed
`--abort-on-error`	Dump core on permanent error (debug option)	All NDB 8.0 releases
`--character-sets-dir=name`	Directory where character sets are	All NDB 8.0 releases
`--database=dbname`, `-d`	Name of the database in which the table is found	All NDB 8.0 releases
`--drop-source`	Drop source table after all rows have been moved	All NDB 8.0 releases

Format	Description	Added, Deprecated, or Removed
--error-insert	Insert random temporary errors (testing option)	All NDB 8.0 releases
--exclude-missing-columns	Ignore extra columns in source or target table	All NDB 8.0 releases
--lossy-conversions, -l	Allow attribute data to be truncated when converted to a smaller type	All NDB 8.0 releases
--promote-attributes, -A	Allow attribute data to be converted to a larger type	All NDB 8.0 releases
--staging-tries=x[,y[,z]]	Specify tries on temporary errors. Format is x[,y[,z]] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms)	All NDB 8.0 releases
--verbose	Enable verbose messages	All NDB 8.0 releases

- --abort-on-error

Property	Value
Command-Line Format	--abort-on-error
Type	Boolean
Default Value	FALSE

Dump core on permanent error (debug option).

- --character-sets-dir=*name*

Property	Value
Command-Line Format	--character-sets-dir=name
Type	String
Default Value	[none]

Directory where character sets are.

- --database=*dbname*, -d

Property	Value
Command-Line Format	--database=dbname
Type	String
Default Value	TEST_DB

Name of the database in which the table is found.

- --drop-source

Property	Value
Command-Line Format	--drop-source
Type	Boolean
Default Value	FALSE

Drop source table after all rows have been moved.

- `--error-insert`

Property	Value
Command-Line Format	`--error-insert`
Type	Boolean
Default Value	`FALSE`

Insert random temporary errors (testing option).

- `--exclude-missing-columns`

Property	Value
Command-Line Format	`--exclude-missing-columns`
Type	Boolean
Default Value	`FALSE`

Ignore extra columns in source or target table.

- `--lossy-conversions`, `-l`

Property	Value
Command-Line Format	`--lossy-conversions`
Type	Boolean
Default Value	`FALSE`

Allow attribute data to be truncated when converted to a smaller type.

- `--promote-attributes`, `-A`

Property	Value
Command-Line Format	`--promote-attributes`
Type	Boolean
Default Value	`FALSE`

Allow attribute data to be converted to a larger type.

- `--staging-tries=`*`x[,y[,z]]`*

Property	Value
Command-Line Format	`--staging-tries=x[,y[,z]]`
Type	String
Default Value	`0,1000,60000`

Specify tries on temporary errors. Format is x[,y[,z]] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms).

- `--verbose`

Property	Value
Command-Line Format	`--verbose`

Property	Value
Type	Boolean
Default Value	FALSE

Enable verbose messages.

22.4.16 ndb_perror — Obtain NDB Error Message Information

ndb_perror shows information about an NDB error, given its error code. This includes the error message, the type of error, and whether the error is permanent or temporary. Added to the MySQL NDB Cluster distribution in NDB 7.6.4, it is intended as a drop-in replacement for perror --ndb.

Usage

```
ndb_perror [options] error_code
```

ndb_perror does not need to access a running NDB Cluster, or any nodes (including SQL nodes). To view information about a given NDB error, invoke the program, using the error code as an argument, like this:

```
shell> ndb_perror 323
NDB error code 323: Invalid nodegroup id, nodegroup already existing: Permanent error: Application erro
```

To display only the error message, invoke ndb_perror with the --silent option (short form -s), as shown here:

```
shell> ndb_perror -s 323
Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

Like perror, ndb_perror accepts multiple error codes:

```
shell> ndb_perror 321 1001
NDB error code 321: Invalid nodegroup id: Permanent error: Application error
NDB error code 1001: Illegal connect string
```

Additional program options for ndb_perror are described later in this section.

ndb_perror replaces perror --ndb, which is deprecated as of NDB 7.6.4 and subject to removal in a future release of MySQL NDB Cluster. To make substitution easier in scripts and other applications that might depend on perror for obtaining NDB error information, ndb_perror supports its own “dummy” --ndb option, which does nothing.

The following table includes all options that are specific to the NDB Cluster program ndb_perror. Additional descriptions follow the table.

Table 22.337 Command-line options for the ndb_perror program

Format	Description	Added, Deprecated, or Removed
--help, -?	Display help text	All NDB 8.0 releases
--ndb	For compatibility with applications depending on old versions of perror; does nothing	All NDB 8.0 releases
--silent,	Show error message only	All NDB 8.0 releases

Format	Description	Added, Deprecated, or Removed
-s --version, -V	Print program version information and exit	All NDB 8.0 releases
--verbose, -v	Verbose output; disable with --silent	All NDB 8.0 releases

Additional Options

- --help, -?

Property	Value
Command-Line Format	--help
Type	Boolean
Default Value	TRUE

Display program help text and exit.

- --ndb

Property	Value
Command-Line Format	--ndb
Type	Boolean
Default Value	TRUE

For compatibility with applications depending on old versions of perror that use that program's --ndb option. The option when used with ndb_perror does nothing, and is ignored by it.

- --silent, -s

Property	Value
Command-Line Format	--silent
Type	Boolean
Default Value	TRUE

Show error message only.

- --version, -V

Property	Value
Command-Line Format	--version
Type	Boolean
Default Value	TRUE

Print program version information and exit.

- --verbose, -v

Property	Value
Command-Line Format	--verbose

Property	Value
Type	Boolean
Default Value	TRUE

Verbose output; disable with `--silent`.

22.4.17 ndb_print_backup_file — Print NDB Backup File Contents

`ndb_print_backup_file` obtains diagnostic information from a cluster backup file.

Usage

```
ndb_print_backup_file file_name
```

`file_name` is the name of a cluster backup file. This can be any of the files (`.Data`, `.ctl`, or `.log` file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see Section 22.5.3.1, “NDB Cluster Backup Concepts”.

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

22.4.18 ndb_print_file — Print NDB Disk Data File Contents

`ndb_print_file` obtains information from an NDB Cluster Disk Data file.

Usage

```
ndb_print_file [-v] [-q] file_name+
```

`file_name` is the name of an NDB Cluster Disk Data file. Multiple filenames are accepted, separated by spaces.

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_file` must be run on an NDB Cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

`ndb_print_file` supports the following options:

- `-v`: Make output verbose.
- `-q`: Suppress output (quiet mode).
- `--help`, `-h`, `-?`: Print help message.

For more information, see Section 22.5.13, “NDB Cluster Disk Data Tables”.

22.4.19 ndb_print_frag_file — Print NDB Fragment List File Contents

ndb_print_frag_file obtains information from a cluster fragment list file. It is intended for use in helping to diagnose issues with data node restarts.

Usage

```
ndb_print_frag_file file_name
```

file_name is the name of a cluster fragment list file, which matches the pattern SX.FragList, where *X* is a digit in the range 2-9 inclusive, and are found in the data node file system of the data node having the node ID *nodeid*, in directories named ndb_*nodeid*_fs/DN/DBDIH/, where *N* is 1 or 2. Each fragment file contains records of the fragments belonging to each NDB table. For more information about cluster fragment files, see NDB Cluster Data Node File System Directory Files.

Like ndb_print_backup_file, ndb_print_sys_file, and ndb_print_schema_file (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server), ndb_print_frag_file must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

Sample Output

```
shell> ndb_print_frag_file /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList
Filename: /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList with size 8192
noOfPages = 1 noOfWords = 182
Table Data

LcpNo[1]: maxGciCompleted: 0 maxGciStarted: 0 lcpId: 0 lcpStatus: invalid
```

22.4.20 ndb_print_schema_file — Print NDB Schema File Contents

ndb_print_schema_file obtains diagnostic information from a cluster schema file.

Usage

```
ndb_print_schema_file file_name
```

file_name is the name of a cluster schema file. For more information about cluster schema files, see NDB Cluster Data Node File System Directory Files.

Like ndb_print_backup_file and ndb_print_sys_file (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) ndb_print_schema_file must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

22.4.21 ndb_print_sys_file — Print NDB System File Contents

ndb_print_sys_file obtains diagnostic information from an NDB Cluster system file.

Usage

```
ndb_print_sys_file file_name
```

file_name is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (DataDir); the path under this directory to system files matches the pattern ndb_#_fs/D#/DBDIH/P#.sysfile. In each case, the # represents a number (not necessarily the same number). For more information, see NDB Cluster Data Node File System Directory Files.

Like ndb_print_backup_file and ndb_print_schema_file (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) ndb_print_backup_file must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

22.4.22 ndb_redo_log_reader — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. ndb_redo_log_reader is intended for use primarily by NDB Cluster developers and Support personnel in debugging and diagnosing problems.

This utility remains under development, and its syntax and behavior are subject to change in future NDB Cluster releases.

Note

Prior to NDB 7.2, this utility was named ndbd_redo_log_reader.

The C++ source files for ndb_redo_log_reader can be found in the directory /storage/ndb/src/kernel/blocks/dblqh/redoLogReader.

The following table includes options that are specific to the NDB Cluster program ndb_redo_log_reader. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_redo_log_reader), see Section 22.4.31, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

Table 22.338 Command-line options for the ndb_redo_log_reader program

Format	Description	Added, Deprecated, or Removed
-dump	Print dump info	All NDB 8.0 releases
-filedescriptors	Print file descriptors only	All NDB 8.0 releases
--help	Print usage information	All NDB 8.0 releases
-lap	Provide lap info, with max GCI started and completed	All NDB 8.0 releases
-mbyte #	Starting megabyte	All NDB 8.0 releases
-mbyteheaders	Show only the first page header of every megabyte in the file	All NDB 8.0 releases
-nocheck	Do not check records for errors	All NDB 8.0 releases
-noprint	Do not print records	All NDB 8.0 releases
-page #	Start with this page	All NDB 8.0 releases
-pageheaders	Show page headers only	All NDB 8.0 releases
-pageindex #	Start with this page index	All NDB 8.0 releases
-twiddle	Bit-shifted dump	All NDB 8.0 releases

Usage

```
ndb_redo_log_reader file_name [options]
```

file_name is the name of a cluster redo log file. redo log files are located in the numbered directories under the data node's data directory (DataDir); the path under this directory to the redo log files matches the pattern ndb_*nodeid*_fs/D#/DBLQH/S#.FragLog. *nodeid* is the data node's node ID. The two instances of # each represent a number (not necessarily the same number); the number following D is in the range 8-39 inclusive; the range of the number following S varies according to the value of the NoOfFragmentLogFiles configuration parameter, whose default value is 16; thus, the default range of the number in the file name is 0-15 inclusive. For more information, see NDB Cluster Data Node File System Directory Files.

The name of the file to be read may be followed by one or more of the options listed here:

- -dump

Property	Value
Command-Line Format	-dump
Type	Boolean
Default Value	FALSE

Print dump info.

-

Property	Value
Command-Line Format	-filedescriptors

Property	Value
Type	Boolean
Default Value	FALSE

-filedescriptors: Print file descriptors only.

Property	Value
Command-Line Format	--help

--help: Print usage information.

- -lap

Property	Value
Command-Line Format	-lap
Type	Boolean
Default Value	FALSE

Provide lap info, with max GCI started and completed.

Property	Value
Command-Line Format	-mbyte #
Type	Numeric
Default Value	0
Minimum Value	0
Maximum Value	15

-mbyte #: Starting megabyte.

is an integer in the range 0 to 15, inclusive.

Property	Value
Command-Line Format	-mbyteheaders
Type	Boolean
Default Value	FALSE

-mbyteheaders: Show only the first page header of every megabyte in the file.

Property	Value
Command-Line Format	-noprint
Type	Boolean
Default Value	FALSE

-noprint: Do not print the contents of the log file.

Property	Value
Command-Line Format	-nocheck
Type	Boolean
Default Value	FALSE

-nocheck: Do not check the log file for errors.

Property	Value
Command-Line Format	`-page #`
Type	Integer
Default Value	`0`
Minimum Value	`0`
Maximum Value	`31`

  `-page #`: Start at this page.

  `#` is an integer in the range 0 to 31, inclusive.

Property	Value
Command-Line Format	`-pageheaders`
Type	Boolean
Default Value	`FALSE`

  `-pageheaders`: Show page headers only.

Property	Value
Command-Line Format	`-pageindex #`
Type	Integer
Default Value	`12`
Minimum Value	`12`
Maximum Value	`8191`

  `-pageindex #`: Start at this page index.

  `#` is an integer between 12 and 8191, inclusive.

- `-twiddle`

Property	Value
Command-Line Format	`-twiddle`
Type	Boolean
Default Value	`FALSE`

  Bit-shifted dump.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_redo_log_reader` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

22.4.23 `ndb_restore` — Restore an NDB Cluster Backup

The cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see Section 22.5.3.2, “Using The NDB Cluster

Management Client to Create a Backup"). This is equal to the number of data nodes in the cluster at the time that the backup was created.

Note

Before using ndb_restore, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See Section 22.5.8, "NDB Cluster Single User Mode", for more information.

The following table includes options that are specific to the NDB Cluster native backup restoration program ndb_restore. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_restore), see Section 22.4.31, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

Table 22.339 Command-line options for the ndb_restore program

Format	Description	Added, Deprecated, or Removed
--append	Append data to a tab-delimited file	All NDB 8.0 releases
--backup_path=dir_name	Path to backup files directory	All NDB 8.0 releases
--backupid=#, -b	Restore from the backup with the given ID	All NDB 8.0 releases
--connect, -c	Alias for --connectstring.	All NDB 8.0 releases
--disable-indexes	Causes indexes from a backup to be ignored; may decrease time needed to restore data.	All NDB 8.0 releases
--dont_ignore_systab_0, -f	Do not ignore system table during restore. Experimental only; not for production use	All NDB 8.0 releases
--exclude-databases=db-list	List of one or more databases to exclude (includes those not named)	All NDB 8.0 releases
--exclude-intermediate-sql-tables[=TRUE|FALSE]	If TRUE (the default), do not restore any intermediate tables (having names prefixed with '#sql-') that were left over from copying ALTER TABLE operations.	All NDB 8.0 releases
--exclude-missing-columns	Causes columns from the backup version of a table that are missing from the version of the table in the database to be ignored.	All NDB 8.0 releases
--exclude-missing-tables	Causes tables from the backup that are missing from the database to be ignored.	All NDB 8.0 releases
--exclude-tables=table-list	List of one or more tables to exclude (includes those in the same database that are not named); each table reference must include the database name	All NDB 8.0 releases
--fields-enclosed-by=char	Fields are enclosed with the indicated character	All NDB 8.0 releases

Format	Description	Added, Deprecated, or Removed
--fields-optionally-enclosed-by	Fields are optionally enclosed with the indicated character	All NDB 8.0 releases
--fields-terminated-by=char	Fields are terminated by the indicated character	All NDB 8.0 releases
--hex	Print binary types in hexadecimal format	All NDB 8.0 releases
--include-databases=db-list	List of one or more databases to restore (excludes those not named)	All NDB 8.0 releases
--include-tables=table-list	List of one or more tables to restore (excludes those in same database that are not named); each table reference must include the database name	All NDB 8.0 releases
--lines-terminated-by=char	Lines are terminated by the indicated character	All NDB 8.0 releases
--lossy-conversions, -L	Allow lossy conversions of column values (type demotions or changes in sign) when restoring data from backup	All NDB 8.0 releases
--no-binlog	If a mysqld is connected and using binary logging, do not log the restored data	All NDB 8.0 releases
--no-restore-disk-objects, -d	Do not restore objects relating to Disk Data	All NDB 8.0 releases
--no-upgrade, -u	Do not upgrade array type for varsize attributes which do not already resize VAR data, and do not change column attributes	All NDB 8.0 releases
--ndb-nodegroup-map=map, -z	Nodegroup map for NDBCLUSTER storage engine. Syntax: list of (source_nodegroup, destination_nodegroup)	All NDB 8.0 releases
--nodeid=#, -n	ID of node where backup was taken	All NDB 8.0 releases
--parallelism=#, -p	Number of parallel transactions to use while restoring data	All NDB 8.0 releases
--preserve-trailing-spaces, -P	Allow preservation of trailing spaces (including padding) when promoting fixed-width string types to variable-width types	All NDB 8.0 releases
--print	Print metadata, data and log to stdout (equivalent to --print_meta --print_data --print_log)	All NDB 8.0 releases
--print_data	Print data to stdout	All NDB 8.0 releases

Format	Description	Added, Deprecated, or Removed
--print_log	Print to stdout	All NDB 8.0 releases
--print_meta	Print metadata to stdout	All NDB 8.0 releases
print-sql-log	Write SQL log to stdout; default is FALSE	All NDB 8.0 releases
--progress-frequency=#	Print status of restoration each given number of seconds	All NDB 8.0 releases
--promote-attributes, -A	Allow attributes to be promoted when restoring data from backup	All NDB 8.0 releases
--rebuild-indexes	Causes multithreaded rebuilding of ordered indexes found in the backup. Number of threads used is determined by setting BuildIndexThreads parameter.	All NDB 8.0 releases
--restore_data, -r	Restore table data and logs into NDB Cluster using the NDB API	All NDB 8.0 releases
--restore_epoch, -e	Restore epoch info into the status table. Convenient on a MySQL Cluster replication slave for starting replication. The row in mysql.ndb_apply_status with id 0 will be updated/inserted.	All NDB 8.0 releases
--restore_meta, -m	Restore metadata to NDB Cluster using the NDB API	All NDB 8.0 releases
--restore-privilege-tables	Restore MySQL privilege tables that were previously moved to NDB.	All NDB 8.0 releases
--rewrite-database=olddb,newdb	Restores to a database with a different name than the original	All NDB 8.0 releases
--skip-broken-objects	Causes missing blob tables in the backup file to be ignored.	All NDB 8.0 releases
--skip-table-check, -s	Skip table structure check during restoring of data	All NDB 8.0 releases
--skip-unknown-objects	Causes schema objects not recognized by ndb_restore to be ignored when restoring a backup made from a newer MySQL Cluster version to an older version.	All NDB 8.0 releases
--tab=dir_name, -T dir_name	Creates a tab-separated .txt file for each table in the given path	All NDB 8.0 releases
--verbose=#	Level of verbosity in output	All NDB 8.0 releases

Typical options for this utility are shown here:

```
ndb_restore [-c connection_string] -n node_id -b backup_id \
      [-m] -r --backup_path=/path/to/backup/files
```

Normally, when restoring from an NDB Cluster backup, ndb_restore requires at a minimum the --nodeid (short form: -n), --backupid (short form: -b), and --backup_path options. In addition, when ndb_restore is used to restore any tables containing unique indexes, you must include --disable-indexes or --rebuild-indexes. (Bug #57782, Bug #11764893)

The -c option is used to specify a connection string which tells ndb_restore where to locate the cluster management server (see Section 22.3.3.3, "NDB Cluster Connection Strings"). If this option is not used, then ndb_restore attempts to connect to a management server on localhost:1186. This utility acts as a cluster API node, and so requires a free connection "slot" to connect to the cluster management server. This means that there must be at least one [api] or [mysqld] section that can be used by it in the cluster config.ini file. It is a good idea to keep at least one empty [api] or [mysqld] section in config.ini that is not being used for a MySQL server or other application for this reason (see Section 22.3.3.7, "Defining SQL and Other API Nodes in an NDB Cluster").

You can verify that ndb_restore is connected to the cluster by using the SHOW command in the ndb_mgm management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

More detailed information about all options used by ndb_restore can be found in the following list:

- --append

Property	Value
Command-Line Format	--append

When used with the --tab and --print_data options, this causes the data to be appended to any existing files having the same names.

- --backup_path=*dir_name*

Property	Value
Command-Line Format	--backup-path=dir_name
Type	Directory name
Default Value	./

The path to the backup directory is required; this is supplied to ndb_restore using the --backup_path option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's DataDir is /var/lib/mysql-cluster, then the backup directory is /var/lib/mysql-cluster/BACKUP, and the backup files for the backup with the ID 3 can be found in /var/lib/mysql-cluster/BACKUP/BACKUP-3. The path may be absolute or relative to the directory in which the ndb_restore executable is located, and may be optionally prefixed with backup_path=.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two storage nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then ndb_restore must be run twice—once for each storage node in the cluster where the backup was taken. However, ndb_restore cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version.

Important

It is not possible to restore a backup made from a newer version of NDB Cluster using an older version of ndb_restore. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of ndb_restore from the newer NDB Cluster version to do so.

> For example, to restore a cluster backup taken from a cluster running NDB Cluster 7.5.14 to a cluster running NDB Cluster 7.4.24, you must use the ndb_restore that comes with the NDB Cluster 7.5.14 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an [api] or [mysqld] section in the cluster config.ini file available for each concurrent ndb_restore process. However, the data files must always be applied before the logs.

- --backupid=#, -b

Property	Value
Command-Line Format	--backupid=#
Type	Numeric
Default Value	none

This option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the Backup *backup_id* completed message displayed upon completion of a backup. (See Section 22.5.3.2, “Using The NDB Cluster Management Client to Create a Backup”.)

> **Important**
>
> When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups will at best result in restoring the cluster to an inconsistent state, and may fail altogether.

In NDB 8.0.15 and later, this option is required.

- --connect, -c

Property	Value
Command-Line Format	--connect
Type	String
Default Value	localhost:1186

Alias for --ndb-connectstring.

- --disable-indexes

Property	Value
Command-Line Format	--disable-indexes

Disable restoration of indexes during restoration of the data from a native NDB backup. Afterwards, you can restore indexes for all tables at once with multithreaded building of indexes using --rebuild-indexes, which should be faster than rebuilding indexes concurrently for very large tables.

- --dont_ignore_systab_0, -f

Property	Value
Command-Line Format	--dont-ignore-systab-0

Normally, when restoring table data and metadata, ndb_restore ignores the copy of the NDB system table that is present in the backup. --dont_ignore_systab_0 causes the system table

to be restored. *This option is intended for experimental and development use only, and is not recommended in a production environment*.

- `--exclude-databases=db-list`

Property	Value
Command-Line Format	`--exclude-databases=db-list`
Type	String
Default Value	

Comma-delimited list of one or more databases which should not be restored.

This option is often used in combination with `--exclude-tables`; see that option's description for further information and examples.

- `--exclude-intermediate-sql-tables[=TRUE|FALSE]`

Property	Value
Command-Line Format	`--exclude-intermediate-sql-tables[=TRUE|FALSE]`
Type	Boolean
Default Value	`TRUE`

When performing copying `ALTER TABLE` operations, `mysqld` creates intermediate tables (whose names are prefixed with `#sql-`). When `TRUE`, the `--exclude-intermediate-sql-tables` option keeps `ndb_restore` from restoring such tables that may have been left over from these operations. This option is `TRUE` by default.

- `--exclude-missing-columns`

Property	Value
Command-Line Format	`--exclude-missing-columns`

It is possible to restore only selected table columns using this option, which causes `ndb_restore` to ignore any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the `--include-*` or `--exclude-*` options described elsewhere in this section to do so, then restore data to the remaining tables using a complementary set of these options.

- `--exclude-missing-tables`

Property	Value
Command-Line Format	`--exclude-missing-tables`

It is possible to restore only selected tables using this option, which causes `ndb_restore` to ignore any tables from the backup that are not found in the target database.

- `--exclude-tables=table-list`

Property	Value
Command-Line Format	`--exclude-tables=table-list`
Type	String
Default Value	

List of one or more tables to exclude; each table reference must include the database name. Often used together with `--exclude-databases`.

When `--exclude-databases` or `--exclude-tables` is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by `ndb_restore`.

This table shows several invocations of `ndb_restore` usng `--exclude-*` options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from an NDB Cluster backup:

Table 22.340 Several invocations of ndb_restore using --exclude-* options, and the effects these options have on restoring from an NDB Cluster backup.

Option	Result
`--exclude-databases=db1`	All tables in all databases except `db1` are restored; no tables in `db1` are restored
`--exclude-databases=db1,db2` (or `--exclude-databases=db1 --exclude-databases=db2`)	All tables in all databases except `db1` and `db2` are restored; no tables in `db1` or `db2` are restored
`--exclude-tables=db1.t1`	All tables except `t1` in database `db1` are restored; all other tables in `db1` are restored; all tables in all other databases are restored
`--exclude-tables=db1.t2,db2.t1` (or `--exclude-tables=db1.t2 --exclude-tables=db2.t1)`	All tables in database `db1` except for `t2` and all tables in database `db2` except for table `t1` are restored; no other tables in `db1` or `db2` are restored; all tables in all other databases are restored

You can use these two options together. For example, the following causes all tables in all databases *except for* databases `db1` and `db2`, and tables `t1` and `t2` in database `db3`, to be restored:

```
shell> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

You can use `--include-*` and `--exclude-*` options together, subject to the following rules:

- The actions of all `--include-*` and `--exclude-*` options are cumulative.
- All `--include-*` and `--exclude-*` options are evaluated in the order passed to ndb_restore, from right to left.
- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table “wins”.

For example, the following set of options causes `ndb_restore` to restore all tables from database `db1` except `db1.t1`, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database `db1` to be restored (including `db1.t1`, but no tables from any other database), because the `--include-databases` option, being farthest to the right, is the first match against database `db1` and thus takes precedence over any other option that matches `db1` or any tables in `db1`:

```
--exclude-tables=db1.t1 --include-databases=db1
```

- `--fields-enclosed-by=char`

Property	Value
Command-Line Format	`--fields-enclosed-by=char`
Type	String
Default Value	

Each column value is enclosed by the string passed to this option (regardless of data type; see the description of `--fields-optionally-enclosed-by`).

- `--fields-optionally-enclosed-by`

Property	Value
Command-Line Format	`--fields-optionally-enclosed-by`
Type	String
Default Value	

The string passed to this option is used to enclose column values containing character data (such as `CHAR`, `VARCHAR`, `BINARY`, `TEXT`, or `ENUM`).

- `--fields-terminated-by=char`

Property	Value
Command-Line Format	`--fields-terminated-by=char`
Type	String
Default Value	`\t (tab)`

The string passed to this option is used to separate column values. The default value is a tab character (`\t`).

- `--hex`

Property	Value
Command-Line Format	`--hex`

If this option is used, all binary values are output in hexadecimal format.

- `--include-databases=db-list`

Property	Value
Command-Line Format	`--include-databases=db-list`
Type	String
Default Value	

Comma-delimited list of one or more databases to restore. Often used together with `--include-tables`; see the description of that option for further information and examples.

- `--include-tables=table-list`

Property	Value
Command-Line Format	`--include-tables=table-list`
Type	String

Property	Value
Default Value	

Comma-delimited list of tables to restore; each table reference must include the database name.

When --include-databases or --include-tables is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by ndb_restore, and are not restored.

The following table shows several invocations of ndb_restore using --include-* options (other options possibly required have been omitted for clarity), and the effects these have on restoring from an NDB Cluster backup:

Table 22.341 Several invocations of ndb_restore using --include-* options, and their effects on restoring from an NDB Cluster backup.

Option	Result
--include-databases=db1	Only tables in database db1 are restored; all tables in all other databases are ignored
--include-databases=db1,db2 (or --include-databases=db1 --include-databases=db2)	Only tables in databases db1 and db2 are restored; all tables in all other databases are ignored
--include-tables=db1.t1	Only table t1 in database db1 is restored; no other tables in db1 or in any other database are restored
--include-tables=db1.t2,db2.t1 (or --include-tables=db1.t2 --include-tables=db2.t1)	Only the table t2 in database db1 and the table t1 in database db2 are restored; no other tables in db1, db2, or any other database are restored

You can also use these two options together. For example, the following causes all tables in databases db1 and db2, together with the tables t1 and t2 in database db3, to be restored (and no other databases or tables):

```
shell> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

It also possible to restore only selected databases, or selected tables from a single database, without any --include-* (or --exclude-*) options, using the syntax shown here:

```
ndb_restore other_options db_name,[db_name[,...] | tbl_name[,tbl_name][,...]]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database

- --lines-terminated-by=*char*

Property	Value
Command-Line Format	--lines-terminated-by=char
Type	String
Default Value	\n (linebreak)

Specifies the string used to end each line of output. The default is a linefeed character (\n).

- --lossy-conversions, -L

Property	Value
Command-Line Format	--lossy-conversions
Type	Boolean
Default Value	FALSE (If option is not used)

This option is intended to complement the --promote-attributes option. Using --lossy-conversions allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for MySQL replication; see Replication of Columns Having Different Data Types, for information about specific type conversions currently supported by attribute demotion.

ndb_restore reports any truncation of data that it performs during lossy conversions once per attribute and column.

- --no-binlog

Property	Value
Command-Line Format	--no-binlog

This option prevents any connected SQL nodes from writing data restored by ndb_restore to their binary logs.

- --no-restore-disk-objects, -d

Property	Value
Command-Line Format	--no-restore-disk-objects
Type	Boolean
Default Value	FALSE

This option stops ndb_restore from restoring any NDB Cluster Disk Data objects, such as tablespaces and log file groups; see Section 22.5.13, “NDB Cluster Disk Data Tables”, for more information about these.

- --no-upgrade, -u

Property	Value
Command-Line Format	--no-upgrade

When using ndb_restore to restore a backup, VARCHAR columns created using the old fixed format are resized and recreated using the variable-width format now employed. This behavior can be overridden by specifying --no-upgrade.

- --ndb-nodegroup-map=*map*, -z

Property	Value
Command-Line Format	--ndb-nodegroup-map=map

This option can be used to restore a backup taken from one node group to a different node group. Its argument is a list of the form *source_node_group, target_node_group*.

- --nodeid=#, -n

Property	Value
Command-Line Format	`--nodeid=#`
Type	Numeric
Default Value	`none`

Specify the node ID of the data node on which the backup was taken.

When restoring to a cluster with different number of data nodes from that where the backup was taken, this information helps identify the correct set or sets of files to be restored to a given node. (In such cases, multiple files usually need to be restored to a single data node.) See Section 22.4.23.1, "Restoring to a different number of data nodes", for additional information and examples.

In NDB 8.0.15 and later, this option is required.

- `--parallelism=#`, `-p`

Property	Value
Command-Line Format	`--parallelism=#`
Type	Numeric
Default Value	`128`
Minimum Value	`1`
Maximum Value	`1024`

`ndb_restore` uses single-row transactions to apply many rows concurrently. This parameter determines the number of parallel transactions (concurrent rows) that an instance of `ndb_restore` tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

The work of performing the inserts is parallelized across the threads in the data nodes involved. This mechanism is employed for restoring bulk data from the `.Data` file—that is, the fuzzy snapshot of the data; it is not used for building or rebuilding indexes. The change log is applied serially; index drops and builds are DDL operations and handled separately. There is no thread-level parallelism on the client side of the restore.

- `--preserve-trailing-spaces`, `-P`

Property	Value
Command-Line Format	`--preserve-trailing-spaces`

Cause trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a `CHAR` column value to `VARCHAR`, or a `BINARY` column value to `VARBINARY`. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

Note

Although you can promote `CHAR` columns to `VARCHAR` and `BINARY` columns to `VARBINARY`, you cannot promote `VARCHAR` columns to `CHAR` or `VARBINARY` columns to `BINARY`.

- `--print`

Property	Value
Command-Line Format	`--print`
Type	Boolean

Property	Value
Default Value	FALSE

Causes ndb_restore to print all data, metadata, and logs to stdout. Equivalent to using the --print_data, --print_meta, and --print_log options together.

Note

Use of --print or any of the --print_* options is in effect performing a dry run. Including one or more of these options causes any output to be redirected to stdout; in such cases, ndb_restore makes no attempt to restore data or metadata to an NDB Cluster.

- --print_data

Property	Value
Command-Line Format	--print-data
Type	Boolean
Default Value	FALSE

Cause ndb_restore to direct its output to stdout. Often used together with one or more of --tab, --fields-enclosed-by, --fields-optionally-enclosed-by, --fields-terminated-by, --hex, and --append.

TEXT and BLOB column values are always truncated. Such values are truncated to the first 256 bytes in the output. This cannot currently be overridden when using --print_data.

- --print_log

Property	Value
Command-Line Format	--print-log
Type	Boolean
Default Value	FALSE

Cause ndb_restore to output its log to stdout.

- --print_meta

Property	Value
Command-Line Format	--print-meta
Type	Boolean
Default Value	FALSE

Print all metadata to stdout.

- print-sql-log

Property	Value
Command-Line Format	print-sql-log
Type	Boolean
Default Value	FALSE

Log SQL statements to stdout. Use the option to enable; normally this behavior is disabled. The option checks before attempting to log whether all the tables being restored have explicitly defined

primary keys; queries on a table having only the hidden primary key implemented by NDB cannot be converted to valid SQL.

The --print-sql-log option was added in NDB 7.5.4. (Bug #13511949)

- --progress-frequency=*N*

Property	Value
Command-Line Format	--progress-frequency=#
Type	Numeric
Default Value	0
Minimum Value	0
Maximum Value	65535

Print a status report each *N* seconds while the backup is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

- --promote-attributes, -A

Property	Value
Command-Line Format	--promote-attributes

ndb_restore supports limited *attribute promotion* in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a “larger, similar” type. For example, data from a CHAR(20) column can be restored to a column declared as VARCHAR(20), VARCHAR(30), or CHAR(30); data from a MEDIUMINT column can be restored to a column of type INT or BIGINT. See Replication of Columns Having Different Data Types, for a table of type conversions currently supported by attribute promotion.

Attribute promotion by ndb_restore must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. ndb_restore cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using ALTER TABLE after restoring the table metadata but before restoring the data.

2. Invoke ndb_restore with the --promote-attributes option (short form -A) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

When converting between character data types and TEXT or BLOB, only conversions between character types (CHAR and VARCHAR) and binary types (BINARY and VARBINARY) can be performed at the same time. For example, you cannot promote an INT column to BIGINT while promoting a VARCHAR column to TEXT in the same invocation of ndb_restore.

Converting between TEXT columns using different character sets is not supported, and is expressly disallowed.

When performing conversions of character or binary types to TEXT or BLOB with ndb_restore, you may notice that it creates and uses one or more staging tables named *table_name*$ST*node_id*. These tables are not needed afterwards, and are normally deleted by ndb_restore following a successful restoration.

- --rebuild-indexes

Property	Value
Command-Line Format	`--rebuild-indexes`

Enable multithreaded rebuilding of the ordered indexes while restoring a native `NDB` backup. The number of threads used for building ordered indexes by `ndb_restore` with this option is controlled by the `BuildIndexThreads` data node configuration parameter and the number of LDMs.

It is necessary to use this option only for the first run of `ndb_restore`; this causes all ordered indexes to be rebuilt without using `--rebuild-indexes` again when restoring subsequent nodes. You should use this option prior to inserting new rows into the database; otherwise, it is possible for a row to be inserted that later causes a unique constraint violation when trying to rebuild the indexes.

Building of ordered indices is parallelized with the number of LDMs by default. Offline index builds performed during node and system restarts can be made faster using the `BuildIndexThreads` data node configuration parameter; this parameter has no effect on dropping and rebuilding of indexes by `ndb_restore`, which is performed online.

Rebuilding of unique indexes uses disk write bandwidth for redo logging and local checkpointing. An insufficient amount of this bandwith can lead to redo buffer overload or log overload errors. In such cases you can run `ndb_restore --rebuild-indexes` again; the process resumes at the point where the error occurred. You can also do this when you have encountered temporary errors. You can repeat execution of `ndb_restore --rebuild-indexes` indefinitely; you may be able to stop such errors by reducing the value of `--parallelism`. If the problem is insufficient space, you can increase the size of the redo log (`FragmentLogFileSize` node configuration parameter), or you can increase the speed at which LCPs are performed (`MaxDiskWriteSpeed` and related parameters), in order to free space more quickly.

- `--restore_data`, `-r`

Property	Value
Command-Line Format	`--restore-data`
Type	Boolean
Default Value	`FALSE`

Output `NDB` table data and logs.

- `--restore_epoch`, `-e`

Property	Value
Command-Line Format	`--restore-epoch`

Add (or restore) epoch information to the cluster replication status table. This is useful for starting replication on an NDB Cluster replication slave. When this option is used, the row in the `mysql.ndb_apply_status` having `0` in the `id` column is updated if it already exists; such a row is inserted if it does not already exist. (See Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”.)

- `--restore_meta`, `-m`

Property	Value
Command-Line Format	`--restore-meta`
Type	Boolean
Default Value	`FALSE`

This option causes `ndb_restore` to print `NDB` table metadata.

The first time you run the ndb_restore restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the --restore_meta (-m) option. Restoring the metadata need be done only on a single data node; this is sufficient to restore it to the entire cluster.

In older versions of NDB Cluster, tables whose schemas were restored using this option used the same number of partitions as they did on the original cluster, even if it had a differing number of data nodes from the new cluster. In NDB 7.5.2 and later, when restoring metadata, this is no longer an issue; ndb_restore now uses the default number of partitions for the target cluster, unless the number of local data manager threads is also changed from what it was for data nodes in the original cluster.

Note

The cluster should have an empty database when starting to restore a backup. (In other words, you should start the data nodes with --initial prior to performing the restore.)

- --restore-privilege-tables

Property	Value
Command-Line Format	--restore-privilege-tables
Type	Boolean
Default Value	FALSE (If option is not used)

ndb_restore does not by default restore distributed MySQL privilege tables. This option causes ndb_restore to restore the privilege tables.

This works only if the privilege tables were converted to NDB before the backup was taken. For more information, see Section 22.5.16, “Distributed MySQL Privileges for NDB Cluster”.

- --rewrite-database=*olddb,newdb*

Property	Value
Command-Line Format	--rewrite-database=olddb,newdb
Type	String
Default Value	none

This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named products, you can restore the data it contains to a database named inventory, use this option as shown here (omitting any other options that might be required):

```
shell> ndb_restore --rewrite-database=product,inventory
```

The option can be employed multiple times in a single invocation of ndb_restore. Thus it is possible to restore simultaneously from a database named db1 to a database named db2 and from a database named db3 to one named db4 using --rewrite-database=db1,db2 --rewrite-database=db3,db4. Other ndb_restore options may be used between multiple occurrences of --rewrite-database.

In the event of conflicts between multiple --rewrite-database options, the last --rewrite-database option used, reading from left to right, is the one that takes effect. For example, if --rewrite-database=db1,db2 --rewrite-database=db1,db3 is used, only --rewrite-database=db1,db3 is honored, and --rewrite-database=db1,db2 is ignored. It is also possible to restore from multiple databases to a single database, so that --rewrite-

`database=db1,db3 --rewrite-database=db2,db3` restores all tables and data from databases `db1` and `db2` into database `db3`.

Important

When restoring from multiple backup databases into a single target database using `--rewrite-database`, no check is made for collisions between table or other object names, and the order in which rows are restored is not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.

- `--skip-broken-objects`

Property	Value
Command-Line Format	`--skip-broken-objects`

This option causes `ndb_restore` to ignore corrupt tables while reading a native `NDB` backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the `--skip-broken-objects` option works only in the case of missing blob parts tables.

- `--skip-table-check`, `-s`

Property	Value
Command-Line Format	`--skip-table-check`

It is possible to restore data without restoring table metadata. By default when doing this, `ndb_restore` fails with an error if a mismatch is found between the table data and the table schema; this option overrides that behavior.

Some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether or not either of the options `--skip-table-check` or `--promote-attributes` is in use. These differences in column definitions are of the following types:

- Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
- Different `STORAGE` settings (`MEMORY`, `DISK`)
- Different default values
- Different distribution key settings

- `--skip-unknown-objects`

Property	Value
Command-Line Format	`--skip-unknown-objects`

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading a native `NDB` backup. This can be used for restoring a backup made from a cluster running (for example) NDB 7.6 to a cluster running NDB Cluster 7.5.

- `--tab=`*`dir_name`*, `-T` *`dir_name`*

Property	Value
Command-Line Format	`--tab=dir_name`
Type	Directory name

Causes --print_data to create dump files, one per table, each named *tbl_name*.txt. It requires as its argument the path to the directory where the files should be saved; use . for the current directory.

- --verbose=#

Property	Value
Command-Line Format	--verbose=#
Type	Numeric
Default Value	1
Minimum Value	0
Maximum Value	255

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

Error reporting.
ndb_restore reports both temporary and permanent errors. In the case of temporary errors, it may able to recover from them, and reports Restore successful, but encountered temporary error, please look at configuration in such cases.

Important

After using ndb_restore to initialize an NDB Cluster for use in circular replication, binary logs on the SQL node acting as the replication slave are not automatically created, and you must cause them to be created manually. To cause the binary logs to be created, issue a SHOW TABLES statement on that SQL node before running START SLAVE. This is a known issue in NDB Cluster.

22.4.23.1 Restoring to a different number of data nodes

It is possible to restore from an NDB backup to a cluster having a different number of data nodes than the original from which the backup was taken. The following two sections discuss, respectively, the cases where the target cluster has a lesser or greater number of data nodes than the source of the backup.

Restoring to Fewer Nodes Than the Original

You can restore to a cluster having fewer data nodes than the original provided that the larger number of nodes is an even multiple of the smaller number. In the following example, we use a backup taken on a cluster having four data nodes to a cluster having two data nodes.

1. The management server for the original cluster is on host host10. The original cluster has four data nodes, with the node IDs and host names shown in the following extract from the management server's config.ini file:

```
[ndbd]
NodeId=2
HostName=host2

[ndbd]
NodeId=4
HostName=host4

[ndbd]
NodeId=6
HostName=host6

[ndbd]
NodeId=8
```

```
HostName=host8
```

We assume that each data node was originally started with `ndbmtd --ndb-connectstring=host10` or the equivalent.

2. Perform a backup in the normal manner. See Section 22.5.3.2, "Using The NDB Cluster Management Client to Create a Backup", for information about how to do this.

3. The files created by the backup on each data node are listed here, where *`N`* is the node ID and *`B`* is the backup ID.

   - `BACKUP-B-0.N.Data`
   - `BACKUP-B.N.ctl`
   - `BACKUP-B.N.log`

   These files are found under `BackupDataDir/BACKUP/BACKUP-B`, on each data node. For the rest of this example, we assume that the backup ID is 1.

   Have all of these files available for later copying to the new data nodes (where they can be accessed on the data node's local file system by `ndb_restore`). It is simplest to copy them all to a single location; we assume that this is what you have done.

4. The management server for the target cluster is on host `host20`, and the target has two data nodes, with the node IDs and host names shown, from the management server `config.ini` file on `host20`:

   ```
   [ndbd]
   NodeId=3
   hostname=host3

   [ndbd]
   NodeId=5
   hostname=host5
   ```

   Each of the data node processes on `host3` and `host5` should be started with `ndbmtd -c host20 --initial` or the equivalent, so that the new (target) cluster starts with clean data node file systems.

5. Copy two different sets of two backup files to each of the target data nodes. For this example, copy the backup files from nodes 2 and 4 from the original cluster to node 3 in the target cluster. These files are listed here:

   - `BACKUP-1-0.2.Data`
   - `BACKUP-1.2.ctl`
   - `BACKUP-1.2.log`
   - `BACKUP-1-0.6.Data`
   - `BACKUP-1.6.ctl`
   - `BACKUP-1.6.log`

   Then copy the backup files from nodes 6 and 8 to node 5; these files are shown in the following list:

   - `BACKUP-1-0.4.Data`
   - `BACKUP-1.4.ctl`
   - `BACKUP-1.4.log`

- BACKUP-1-0.8.Data
- BACKUP-1.8.ctl
- BACKUP-1.8.log

For the remainder of this example, we assume that the respective backup files have been saved to the directory /BACKUP-1 on each of nodes 3 and 5.

6. On each of the two target data nodes, you must restore from both sets of backups. First, restore the backups from nodes 2 and 4 to node 3 by invoking ndb_restore on host3 as shown here:

```
shell> ndb_restore -c host20 --nodeid=2 --backupid=1 --restore_data --backup_path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=4 --backupid=1 --restore_data --backup_path=/BACKUP-1
```

Then restore the backups from nodes 6 and 8 to node 5 by invoking ndb_restore on host5, like this:

```
shell> ndb_restore -c host20 --nodeid=6 --backupid=1 --restore_data --backup_path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=8 --backupid=1 --restore_data --backup_path=/BACKUP-1
```

Restoring to More Nodes Than the Original

The node ID specified for a given ndb_restore command is that of the node in the original backup and not that of the data node to restore it to. When performing a backup using the method described in this section, ndb_restore connects to the management server and obtains a list of data nodes in the cluster the backup is being restored to. The restored data is distributed accordingly, so that the number of nodes in the target cluster does not need to be to be known or calculated when performing the backup.

Note

When changing the total number of LCP threads or LQH threads per node group, you should recreate the schema from backup created using mysqldump.

1. *Create the backup of the data*. You can do this by invoking the ndb_mgm client START BACKUP command from the system shell, like this:

```
shell> ndb_mgm -e "START BACKUP 1"
```

This assumes that the desired backup ID is 1.

2. Create a backup of the schema. This step is necessary only if the total number of LCP threads or LQH threads per node group is changed.

```
shell> mysqldump --no-data --routines --events --triggers --databases > myschema.sql
```

Important

Once you have created the NDB native backup using ndb_mgm, you must not make any schema changes before creating the backup of the schema, if you do so.

3. Copy the backup directory to the new cluster. For example if the backup you want to restore has ID 1 and BackupDataDir = /backups/node_*nodeid*, then the path to the backup on this node is /backups/node_1/BACKUP/BACKUP-1. Inside this directory there are three files, listed here:

- BACKUP-1-0.1.Data

- BACKUP-1.1.ctl
- BACKUP-1.1.log

You should copy the entire directory to the new node.

If you needed to create a schema file, copy this to a location on an SQL node where it can be read by mysqld.

There is no requirement for the backup to be restored from a specific node or nodes.

To restore from the backup just created, perform the following steps:

1. *Restore the schema*.

   - If you created a separate schema backup file using mysqldump, import this file using the mysql client, similar to what is shown here:

     ```
     shell> mysql < myschema.sql
     ```

     When importing the schema file, you may need to specify the --user and --password options (and possibly others) in addition to what is shown, in order for the mysql client to be able to connect to the MySQL server.

   - If you did *not* need to create a schema file, you can re-create the schema using ndb_restore --restore_meta (short form -m), similar to what is shown here:

     ```
     shell> ndb_restore --nodeid=1 --backupid=1 --restore_meta --backup-path=/backups/node_1/BACKUP/BACKUP
     ```

     ndb_restore must be able to contact the management server; add the --ndb-connectstring option if and as needed to make this possible.

2. *Restore the data*. This needs to be done once for each data node in the original cluster, each time using that data node's node ID. Assuming that there were 4 data nodes originally, the set of commands required would look something like this:

   ```
   ndb_restore --nodeid=1 --backupid=1 --restore_data --backup_path=/backups/node_1/BACKUP/BACKUP-1 --disa
   ndb_restore --nodeid=2 --backupid=1 --restore_data --backup_path=/backups/node_2/BACKUP/BACKUP-1 --disa
   ndb_restore --nodeid=3 --backupid=1 --restore_data --backup_path=/backups/node_3/BACKUP/BACKUP-1 --disa
   ndb_restore --nodeid=4 --backupid=1 --restore_data --backup_path=/backups/node_4/BACKUP/BACKUP-1 --disa
   ```

   These can be run in parallel.

   Be sure to add the --ndb-connectstring option as needed.

3. *Rebuild the indexes*. These were disabled by the --disable-indexes option used in the commands just shown. Recreating the indexes avoids errors due to the restore not being consistent at all points. Rebuilding the indexes can also improve performance in some cases. To rebuild the indexes, execute the following command once, on a single node:

   ```
   shell> ndb_restore --nodeid=1 --backupid=1 --backup_path=/backups/node_1/BACKUP/BACKUP-1 --rebuild-inde
   ```

   As mentioned previously, you may need to add the --ndb-connectstring option, so that ndb_restore can contact the management server.

22.4.24 ndb_select_all — Print Rows from an NDB Table

ndb_select_all prints all rows from an NDB table to stdout.

Usage

```
ndb_select_all -c connection_string tbl_name -d db_name [> file_name]
```

The following table includes options that are specific to the NDB Cluster native backup restoration program ndb_select_all. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_select_all), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.342 Command-line options for the ndb_select_all program

Format	Description	Added, Deprecated, or Removed
--database=dbname, -d	Name of the database in which the table is found	All NDB 8.0 releases
--parallelism=#, -p	Degree of parallelism	All NDB 8.0 releases
--lock=#, -l	Lock type	All NDB 8.0 releases
--order=index, -o	Sort resultset according to index whose name is supplied	All NDB 8.0 releases
--descending, -z	Sort resultset in descending order (requires order flag)	All NDB 8.0 releases
--header, -h	Print header (set to 0|FALSE to disable headers in output)	All NDB 8.0 releases
--useHexFormat, -x	Output numbers in hexadecimal format	All NDB 8.0 releases
--delimiter=char, -D	Set a column delimiter	All NDB 8.0 releases
--disk	Print disk references (useful only for Disk Data tables having nonindexed columns)	All NDB 8.0 releases
--rowid	Print rowid	All NDB 8.0 releases
--gci	Include GCI in output	All NDB 8.0 releases
--gci64	Include GCI and row epoch in output	All NDB 8.0 releases
--tupscan, -t	Scan in tup order	All NDB 8.0 releases
--nodata	Do not print table column data	All NDB 8.0 releases

- --database=*dbname*, -d *dbname*

  Name of the database in which the table is found. The default value is TEST_DB.

- parallelism=#, -p #

  Specifies the degree of parallelism.

- `--lock=lock_type`, `-l lock_type`

  Employs a lock when reading the table. Possible values for *`lock_type`* are:

  - `0`: Read lock
  - `1`: Read lock with hold
  - `2`: Exclusive read lock

  There is no default value for this option.

- `--order=index_name`, `-o index_name`

  Orders the output according to the index named *`index_name`*.

  Note

  This is the name of an index, not of a column; the index must have been explicitly named when created.

- `--descending`, `-z`

  Sorts the output in descending order. This option can be used only in conjunction with the `-o` (`--order`) option.

- `--header=FALSE`

  Excludes column headers from the output.

- `--useHexFormat -x`

  Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- `--delimiter=character`, `-D character`

  Causes the *`character`* to be used as a column delimiter. Only table data columns are separated by this delimiter.

  The default delimiter is the tab character.

- `--disk`

  Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

- `--rowid`

  Adds a `ROWID` column providing information about the fragments in which rows are stored.

- `--gci`

  Adds a `GCI` column to the output showing the global checkpoint at which each row was last updated. See Section 22.1, “NDB Cluster Overview”, and Section 22.5.6.2, “NDB Cluster Log Events”, for more information about checkpoints.

- `--gci64`

  Adds a `ROW$GCI64` column to the output showing the global checkpoint at which each row was last updated, as well as the number of the epoch in which this update occurred.

- `--tupscan`, `-t`

Scan the table in the order of the tuples.

- `--nodata`

  Causes any table data to be omitted.

Sample Output

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+----+-----------+
| id | name      |
+----+-----------+
|  3 | shark     |
|  6 | puffer    |
|  2 | tuna      |
|  4 | manta ray |
|  5 | grouper   |
|  1 | guppy     |
+----+-----------+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned

NDBT_ProgramExit: 0 - OK
```

All string values are enclosed by square brackets (`[...]`) in the output of `ndb_select_all`. For another example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (
    id INT(11) NOT NULL AUTO_INCREMENT,
    name VARCHAR(25) NOT NULL,
    breed VARCHAR(50) NOT NULL,
    PRIMARY KEY pk (id),
    KEY ix (name)
)
TABLESPACE ts STORAGE DISK
ENGINE=NDBCLUSTER;

INSERT INTO dogs VALUES
    ('', 'Lassie', 'collie'),
    ('', 'Scooby-Doo', 'Great Dane'),
    ('', 'Rin-Tin-Tin', 'Alsatian'),
    ('', 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional `ndb_select_all` options:

```
shell> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI     id name          breed        DISK_REF
834461  2  [Scooby-Doo]  [Great Dane] [ m_file_no: 0 m_page: 98 m_page_idx: 0 ]
834878  4  [Rosscoe]     [Mutt]       [ m_file_no: 0 m_page: 98 m_page_idx: 16 ]
834463  3  [Rin-Tin-Tin] [Alsatian]   [ m_file_no: 0 m_page: 34 m_page_idx: 0 ]
835657  1  [Lassie]      [Collie]     [ m_file_no: 0 m_page: 66 m_page_idx: 0 ]
4 rows returned
```

```
NDBT_ProgramExit: 0 - OK
```

22.4.25 ndb_select_count — Print Row Counts for NDB Tables

ndb_select_count prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement SELECT COUNT(*) FROM *tbl_name*.

Usage

```
ndb_select_count [-c connection_string] -ddb_name tbl_name[, tbl_name2[, ...]]
```

The following table includes options that are specific to the NDB Cluster native backup restoration program ndb_select_count. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_select_count), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.343 Command-line options for the ndb_select_count program

Format	Description	Added, Deprecated, or Removed
--database=dbname, -d	Name of the database in which the table is found	All NDB 8.0 releases
--parallelism=#, -p	Degree of parallelism	All NDB 8.0 releases
--lock=#, -l	Lock type	All NDB 8.0 releases

You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

Sample Output

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs

NDBT_ProgramExit: 0 - OK
```

22.4.26 ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster

ndb_setup.py starts the NDB Cluster Auto-Installer and opens the installer's Start page in the default Web browser.

Important

This program is intended to be invoked as a normal user, and not with the mysql, system root or other administrative account.

This section describes usage of and program options for the command-line tool only. For information about using the Auto-Installer GUI that is spawned when ndb_setup.py is invoked, see The NDB Cluster Auto-Installer (NDB 7.5).

Usage

All platforms:

```
ndb_setup.py [options]
```

Additionally, on Windows platforms only:

```
setup.bat [options]
```

The following table includes all options that are supported by the NDB Cluster installation and configuration program ndb_setup.py. Additional descriptions follow the table.

Table 22.344 Command-line options for the ndb_setup.py program

Format	Description	Added, Deprecated, or Removed
--browser-start-page=filename, -s	Page that the web browser opens when starting.	All NDB 8.0 releases
--ca-certs-file=filename, -a	File containing list of client certificates allowed to connect to the server	All NDB 8.0 releases
--cert-file=filename, -c	File containing X509 certificate that identifies the server. (Default: cfg.pem)	All NDB 8.0 releases
--debug-level=level, -d	Python logging module debug level. One of DEBUG, INFO, WARNING (default), ERROR, or CRITICAL.	All NDB 8.0 releases
--help, -h	Print help message	All NDB 8.0 releases
--key-file=file, -k	Specify file containing private key (if not included in --cert-file)	All NDB 8.0 releases
--no-browser, -n	Do not open the start page in a browser, merely start the tool	All NDB 8.0 releases
--port=#, -p	Specify the port used by the web server	All NDB 8.0 releases
--server-log-file=file, o	Log requests to this file. Use '-' to force logging to stderr instead.	All NDB 8.0 releases
--server-name=name, -N	The name of the server to connect with	All NDB 8.0 releases
--use-http, -H	Use unencrypted (HTTP) client/server connection	All NDB 8.0 releases
--use-https, -S	Use encrypted (HTTPS) client/server connection	All NDB 8.0 releases

- --browser-start-page=*file*, -s

Property	Value
Command-Line Format	`--browser-start-page=filename`
Type	String
Default Value	`index.html`

Specify the file to open in the browser as the installation and configuration Start page. The default is `index.html`.

- `--ca-certs-file=file`, `-a`

Property	Value
Command-Line Format	`--ca-certs-file=filename`
Type	File name
Default Value	`[none]`

Specify a file containing a list of client certificates which are allowed to connect to the server. The default is an empty string, which means that no client authentication is used.

- `--cert-file=file`, `-c`

Property	Value
Command-Line Format	`--cert-file=filename`
Type	File name
Default Value	`/usr/share/mysql/mcc/cfg.pem`

Specify a file containing an X509 certificate which identifies the server. It is possible for the certificate to be self-signed. The default is `cfg.pem`.

- `--debug-level=level`, `-d`

Property	Value
Command-Line Format	`--debug-level=level`
Type	Enumeration
Default Value	`WARNING`

Valid Values	`WARNING`
	`DEBUG`
	`INFO`
	`ERROR`
	`CRITICAL`

Set the Python logging module debug level. This is one of `DEBUG`, `INFO`, `WARNING`, `ERROR`, or `CRITICAL`. `WARNING` is the default.

- `--help`, `-h`

Property	Value
Command-Line Format	`--help`

Print a help message.

- `--key-file=file`, `-d`

Property	Value
Command-Line Format	`--key-file=file`
Type	File name
Default Value	`[none]`

Specify a file containing the private key if this is not included in the X509 certificate file (`--cert-file`). The default is an empty string, which means that no such file is used.

- `--no-browser`, `-n`

Property	Value
Command-Line Format	`--no-browser`

Start the installation and configuration tool, but do not open the Start page in a browser.

- `--port=#`, `-p`

Property	Value
Command-Line Format	`--port=#`
Type	Numeric
Default Value	`8081`
Minimum Value	`1`
Maximum Value	`65535`

Set the port used by the web server. The default is 8081.

- `--server-log-file=file`, `-o`

Property	Value
Command-Line Format	`--server-log-file=file` `o`
Type	File name
Default Value	`ndb_setup.log`
Valid Values	`ndb_setup.log` `-` (Log to stderr)

Log requests to this file. The default is `ndb_setup.log`. To specify logging to `stderr`, rather than to a file, use a `-` (dash character) for the file name.

- `--server-name=host`, `-N`

Property	Value
Command-Line Format	`--server-name=name`
Type	String
Default Value	`localhost`

Specify the host name or IP address for the browser to use when connecting. The default is `localhost`.

- `--use-http`, `-H`

Property	Value
Command-Line Format	`--use-http`

Make the browser use HTTP to connect with the server. This means that the connection is unencrypted and not secured in any way.

- `--use-https`, `-S`

Property	Value
Command-Line Format	`--use-https`

Make the browser use a secure (HTTPS) connection with the server.

22.4.27 ndb_show_tables — Display List of NDB Tables

`ndb_show_tables` displays a list of all `NDB` database objects in the cluster. By default, this includes not only both user-created tables and `NDB` system tables, but `NDB`-specific indexes, internal triggers, and NDB Cluster Disk Data objects as well.

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_show_tables`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_show_tables`), see Section 22.4.31, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

Table 22.345 Command-line options for the ndb_show_tables program

Format	Description	Added, Deprecated, or Removed
`--database=string`, `-d`	Specifies the database in which the table is found	All NDB 8.0 releases
`--loops=#`, `-l`	Number of times to repeat output	All NDB 8.0 releases
`--parsable`, `-p`	Return output suitable for MySQL LOAD DATA INFILE statement	All NDB 8.0 releases
`--show-temp-status`	Show table temporary flag	All NDB 8.0 releases
`--type=#`, `-t`	Limit output to objects of this type	All NDB 8.0 releases
`--unqualified`, `-u`	Do not qualify table names	All NDB 8.0 releases

Usage

```
ndb_show_tables [-c connection_string]
```

- `--database`, `-d`

Specifies the name of the database in which the tables are found. If this option has not been specified, and no tables are found in the `TEST_DB` database, `ndb_show_tables` issues a warning.

- `--loops`, `-l`

Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- `--parsable`, `-p`

  Using this option causes the output to be in a format suitable for use with `LOAD DATA`.

- `--show-temp-status`

  If specified, this causes temporary tables to be displayed.

- `--type`, `-t`

  Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

  - `1`: System table
  - `2`: User-created table
  - `3`: Unique hash index

  Any other value causes all `NDB` database objects to be listed (the default).

- `--unqualified`, `-u`

  If specified, this causes unqualified object names to be displayed.

Note

Only user-created NDB Cluster tables may be accessed from MySQL; system tables such as `SYSTAB_0` are not visible to `mysqld`. However, you can examine the contents of system tables using `NDB` API applications such as `ndb_select_all` (see Section 22.4.24, “`ndb_select_all` — Print Rows from an NDB Table”).

22.4.28 `ndb_size.pl` — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the `NDBCLUSTER` storage engine. Unlike the other utilities discussed in this section, it does not require access to an NDB Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

Requirements

- A running MySQL server. The server instance does not have to provide support for NDB Cluster.
- A working installation of Perl.
- The `DBI` module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using `GRANT USAGE ON *db_name*.*`—where *`db_name`* is the name of the database to be examined—is sufficient for this purpose.

`ndb_size.pl` can also be found in the MySQL sources in `storage/ndb/tools`.

The following table includes options that are specific to the NDB Cluster program `ndb_size.pl`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including

ndb_size.pl), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.346 Command-line options for the ndb_size.pl program

Format	Description	Added, Deprecated, or Removed
--database=dbname	The database or databases to examine; accepts a comma-delimited list; the default is ALL (use all databases found on the server)	All NDB 8.0 releases
--hostname[:port]	Specify host and optional port as host[:port]	All NDB 8.0 releases
--socket=file_name	Specify a socket to connect to	All NDB 8.0 releases
--user=string	Specify a MySQL user name	All NDB 8.0 releases
--password=string	Specify a MySQL user password	All NDB 8.0 releases
--format=string	Set output format (text or HTML)	All NDB 8.0 releases
--excludetables=tbl_list	Skip any tables in a comma-separated list of tables	All NDB 8.0 releases
--excludedbs=db_list	Skip any databases in a comma-separated list of databases	All NDB 8.0 releases
--savequeries=file	Saves all queries to the database into the file specified	All NDB 8.0 releases
--loadqueries=file	Loads all queries from the file specified; does not connect to a database	All NDB 8.0 releases
--real_table_name=table	Designates a table to handle unique index size calculations	All NDB 8.0 releases

Usage

```
perl ndb_size.pl [--database={db_name|ALL}] [--hostname=host[:port]] [--socket=socket] \
      [--user=user] [--password=password]  \
      [--help|-h] [--format={html|text}] \
      [--loadqueries=file_name] [--savequeries=file_name]
```

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the --database option; the default behavior can be made explicit by using ALL for the name of the database. You can also exclude one or more databases by using the --excludedbs option with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional --excludetables option. A host name can be specified using --hostname; the default is localhost. You can specify a port in addition to the host using *host*:*port* format for the value of --hostname. The default port number is 3306. If necessary, you can also specify a socket; the default is /var/lib/mysql.sock. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the --format option; this can take either of the values html or text, with text being the default. An example of the text output is shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
----------------------------------------------------
Connected to: DBI:mysql:host=localhost;mysql_socket=/tmp/mysql.sock

Including information for versions: 4.1, 5.0, 5.1
```

```
test.t1
-------

DataMemory for Columns (* means varsized DataMemory):
         Column Name            Type  Varsized   Key  4.1  5.0   5.1
     HIDDEN_NDB_PKEY          bigint             PRI    8    8     8
                  c2     varchar(50)         Y         52   52    4*
                  c1         int(11)                    4    4     4
                                                       --   --    --
Fixed Size Columns DM/Row                              64   64    12
   Varsize Columns DM/Row                               0    0     4

DataMemory for Indexes:
   Index Name                Type        4.1        5.0        5.1
      PRIMARY                BTREE        16         16         16
                                          --         --         --
       Total Index DM/Row                 16         16         16

IndexMemory for Indexes:
               Index Name        4.1        5.0        5.1
                  PRIMARY         33         16         16
                                  --         --         --
           Indexes IM/Row         33         16         16

Summary (for THIS table):
                                 4.1        5.0        5.1
    Fixed Overhead DM/Row         12         12         16
           NULL Bytes/Row          4          4          4
           DataMemory/Row         96         96         48
                    (Includes overhead, bitmap and indexes)

Parameter Minimum Requirements
------------------------------
* indicates greater than default

               Parameter     Default        4.1         5.0         5.1
          DataMemory (KB)       81920          0           0           0
       NoOfOrderedIndexes         128          1           1           1
                NoOfTables         128          1           1           1
         IndexMemory (KB)       18432          0           0           0
    NoOfUniqueHashIndexes          64          0           0           0
           NoOfAttributes        1000          3           3           3
             NoOfTriggers         768          5           5           5
```

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using can be saved to a file using `--savequeries`; a file containing such arrays to be read during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.)

The output from this script includes the following information:

- Minimum values for the DataMemory, IndexMemory, MaxNoOfTables, MaxNoOfAttributes, MaxNoOfOrderedIndexes, and MaxNoOfTriggers configuration parameters required to accommodate the tables analyzed.
- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The IndexMemory and DataMemory required per table and table row.

22.4.29 ndb_top — View CPU usage information for NDB threads

ndb_top displays running information in the terminal about CPU usage by NDB threads on an NDB Cluster data node. Each thread is represented by two rows in the output, the first showing system statistics, the second showing the measured statistics for the thread.

ndb_top is available beginning with MySQL NDB Cluster 7.6.3.

Usage

```
ndb_top [-h hostname] [-t port] [-u user] [-p pass] [-n node_id]
```

ndb_top connects to a MySQL Server running as an SQL node of the cluster. By default, it attempts to connect to a mysqld running on localhost and port 3306, as the MySQL root user with no password specified. You can override the default host and port using, respectively, --host (-h) and --port (-t). To specify a MySQL user and password, use the --user (-u) and --passwd (-p) options. This user must be able to read tables in the ndbinfo database (ndb_top uses information from ndbinfo.cpustat and related tables).

For more information about MySQL user accounts and passwords, see Section 6.3, “User Account Management”, as well as Section 6.2, “The Access Privilege System”.

Output is available as plain text or an ASCII graph; you can specify this using the --text (-x) and --graph (-g) options, respectively. These two display modes provide the same information; they can be used concurrently. At least one display mode must be in use.

Color display of the graph is supported and enabled by default (--color or -c option). With color support enabled, the graph display shows OS user time in blue, OS system time in green, and idle time as blank. For measured load, blue is used for execution time, yellow for send time, red for time spent in send buffer full waits, and blank spaces for idle time. The percentage shown in the graph display is the sum of percentages for all threads which are not idle. Colors are not currently configurable; you can use grayscale instead by using --skip-color.

The sorted view (--sort, -r) is based on the maximum of the measured load and the load reported by the OS. Display of these can be enabled and disabled using the --measured-load (-m) and --os-load (-o) options. Display of at least one of these loads must be enabled.

The program tries to obtain statistics from a data node having the node ID given by the --node-id (-n) option; if unspecified, this is 1. ndb_top cannot provide information about other types of nodes.

The view adjusts itself to the height and width of the terminal window; the minimum supported width is 76 characters.

Once started, ndb_top runs continuously until forced to exit; you can quit the program using Ctrl-C. The display updates once per second; to set a different delay interval, use --sleep-time (-s).

Note

ndb_top is available on Mac OS X, Linux, and Solaris. It is not currently supported on Windows platforms.

The following table includes all options that are specific to the NDB Cluster program ndb_top. Additional descriptions follow the table.

Table 22.347 Command-line options for the ndb_top program

Format	Description	Added, Deprecated, or Removed
--color, -c	Show ASCII graphs in color; use --skip-colors to disable	All NDB 8.0 releases
--graph, -g	Display data using graphs; use --skip-graphs to disable	All NDB 8.0 releases
--help, -?	Show program usage information	All NDB 8.0 releases
--host[=name], -h	Host name or IP address of MySQL Server to connect to	All NDB 8.0 releases
--measured-load, -m	Show measured load by thread	All NDB 8.0 releases
--node-id[=#], -n	Watch node having this node ID	All NDB 8.0 releases
--os-load, -o	Show load measured by operating system	All NDB 8.0 releases
--passwd[=password], -p	Connect using this password	All NDB 8.0 releases REMOVED: NDB 7.6.4
--password[=password], -p	Connect using this password	All NDB 8.0 releases
--port[=#], -t (<=7.6.5), -P (>=7.6.6)	Port number to use when connecting to MySQL Server	All NDB 8.0 releases
--sleep-time[=seconds], -s	Time to wait between display refreshes, in seconds	All NDB 8.0 releases
--socket, -S	Socket file to use for connection.	All NDB 8.0 releases
--sort, -r	Sort threads by usage; use --skip-sort to disable	All NDB 8.0 releases
--text, -x (<=7.6.5), -t (>=7.6.6)	Display data using text	All NDB 8.0 releases
--user[=name], -u	Connect as this MySQL user	All NDB 8.0 releases

In NDB 7.6.6 and later, ndb_top also supports the common NDB program options --defaults-file, --defaults-extra-file, --print-defaults, --no-defaults, and --defaults-group-suffix. (Bug #86614, Bug #26236298)

Additional Options

- --color, -c

Property	Value
Command-Line Format	--color
Type	Boolean
Default Value	TRUE

Show ASCII graphs in color; use --skip-colors to disable.

- --graph, -g

Property	Value
Command-Line Format	--graph
Type	Boolean
Default Value	TRUE

Display data using graphs; use --skip-graphs to disable. This option or --text must be true; both options may be true.

- --help, -?

Property	Value
Command-Line Format	--help
Type	Boolean
Default Value	TRUE

Show program usage information.

- --host[=*name*], -h

Property	Value
Command-Line Format	--host[=name]
Type	String
Default Value	localhost

Host name or IP address of MySQL Server to connect to.

- --measured-load, -m

Property	Value
Command-Line Format	--measured-load
Type	Boolean
Default Value	FALSE

Show measured load by thread. This option or --os-load must be true; both options may be true.

- --node-id[=*#*], -n

Property	Value
Command-Line Format	--node-id[=#]
Type	Integer
Default Value	1

Watch the data node having this node ID.

- --os-load, -o

Property	Value
Command-Line Format	--os-load
Type	Boolean
Default Value	TRUE

Show load measured by operating system. This option or --measured-load must be true; both options may be true.

- --passwd[=*password*], -p

Property	Value
Command-Line Format	--passwd[=password]
Type	Boolean
Default Value	NULL

Connect using this password.

This option is deprecated in NDB 7.6.4. It is removed in NDB 7.6.6, where it is replaced by the --password option. (Bug #26907833)

- --password[=*password*], -p

Property	Value
Command-Line Format	--password[=password]
Type	Boolean
Default Value	NULL

Connect using this password.

This option was added in NDB 7.6.6 as a replacement for the --passwd option used previously. (Bug #26907833)

- --port[=*#*], -t (NDB 7.6.6 and later: -P)

Property	Value
Command-Line Format	--port[=#]
Type	Integer
Default Value	3306

Port number to use when connecting to MySQL Server.

~~Beginning with NDB 7.6.6, the short form for this option is -P, and -t is repurposed as the short form for the --text option. (Bug #26907833)~~

- `--sleep-time[=seconds]`, `-s`

Property	Value
Command-Line Format	`--sleep-time[=seconds]`
Type	Integer
Default Value	`1`

Time to wait between display refreshes, in seconds.

- `--socket=path/to/file`, `-S`

Property	Value
Command-Line Format	`--socket`
Type	Path name
Default Value	`[none]`

Use the specified socket file for the connection.

Added in NDB 7.6.6. (Bug #86614, Bug #26236298)

- `--sort`, `-r`

Property	Value
Command-Line Format	`--sort`
Type	Boolean
Default Value	`TRUE`

Sort threads by usage; use `--skip-sort` to disable.

- `--text`, `-x` (NDB 7.6.6 and later: `-t`)

Property	Value
Command-Line Format	`--text`
Type	Boolean
Default Value	`FALSE`

Display data using text. This option or `--graph` must be true; both options may be true.

Beginning with NDB 7.6.6, the short form for this option is `-t` and support for `-x` is removed. (Bug #26907833)

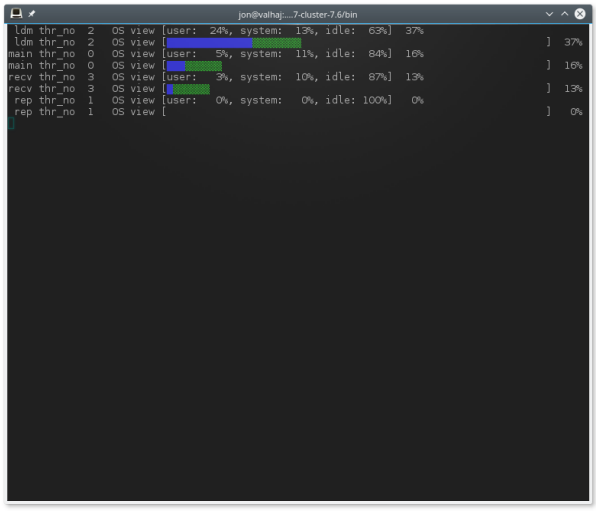
- `--user[=name]`, `-u`

Property	Value
Command-Line Format	`--user[=name]`
Type	String
Default Value	`root`

Connect as this MySQL user.

Sample Output. The next figure shows `ndb_top` running in a terminal window on a Linux system with an `ndbmtd` data node under a moderate load. Here, the program has been invoked using `ndb_top -n8 -x` to provide both text and graph output:

Figure 22.25 ndb_top Running in Terminal



22.4.30 ndb_waiter — Wait for NDB Cluster to Reach a Given Status

ndb_waiter repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the --timeout limit is exceeded, then exits. By default, it waits for the cluster to achieve STARTED status, in which all nodes have started and connected to the cluster. This can be overridden using the --no-contact and --not-started options.

The node states reported by this utility are as follows:

- NO_CONTACT: The node cannot be contacted.
- UNKNOWN: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a START or RESTART command from the management server, but has not yet acted on it.
- NOT_STARTED: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's RESTART command.
- STARTING: The node's ndbd process has started, but the node has not yet joined the cluster.
- STARTED: The node is operational, and has joined the cluster.
- SHUTTING_DOWN: The node is shutting down.
- SINGLE USER MODE: This is shown for all cluster data nodes when the cluster is in single user mode.

The following table includes options that are specific to the NDB Cluster native backup restoration program ndb_waiter. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_waiter), see Section 22.4.31, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 22.348 Command-line options for the ndb_waiter program

Format	Description	Added, Deprecated, or Removed
--no-contact, -n	Wait for cluster to reach NO CONTACT state	All NDB 8.0 releases
--not-started	Wait for cluster to reach NOT STARTED state	All NDB 8.0 releases

Format	Description	Added, Deprecated, or Removed
--single-user	Wait for cluster to enter single user mode	All NDB 8.0 releases
--timeout=#, -t	Wait this many seconds, then exit whether or not cluster has reached desired state; default is 2 minutes (120 seconds)	All NDB 8.0 releases
--nowait-nodes=list	List of nodes not to be waited for.	All NDB 8.0 releases
--wait-nodes=list, -w	List of nodes to be waited for.	All NDB 8.0 releases

Usage

```
ndb_waiter [-c connection_string]
```

Additional Options

- --no-contact, -n

  Instead of waiting for the STARTED state, ndb_waiter continues running until the cluster reaches NO_CONTACT status before exiting.

- --not-started

  Instead of waiting for the STARTED state, ndb_waiter continues running until the cluster reaches NOT_STARTED status before exiting.

- --timeout=*seconds*, -t *seconds*

  Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- --single-user

  The program waits for the cluster to enter single user mode.

- --nowait-nodes=*list*

  When this option is used, ndb_waiter does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

  ```
  shell> ndb_waiter --nowait-nodes=1,3,7-9
  ```

  Important

  Do *not* use this option together with the --wait-nodes option.

- --wait-nodes=*list*, -w *list*

  When this option is used, ndb_waiter waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

  ```
  shell> ndb_waiter --wait-nodes=2,4-6,10
  ```

Important

Do *not* use this option together with the `--nowait-nodes` option.

Sample Output. Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by `...`) are omitted.

```
shell> ./ndb_waiter -c localhost

Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED

NDBT_ProgramExit: 0 - OK
```

Note

If no connection string is specified, then `ndb_waiter` tries to connect to a management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

22.4.31 Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs

All NDB Cluster programs accept the options described in this section, with the following exceptions:

- `mysqld`
- `ndb_print_backup_file`
- `ndb_print_schema_file`
- `ndb_print_sys_file`

Note

Users of earlier NDB Cluster versions should note that some of these options have been changed to make them consistent with one another, and also with `mysqld`. You can use the `--help` option with any NDB Cluster program—with the exception of `ndb_print_backup_file`, `ndb_print_schema_file`, and `ndb_print_sys_file`—to view a list of the options which the program supports.

The options in the following table are common to all NDB Cluster executables (except those noted previously in this section).

Table 22.349 Command-line options common to all MySQL NDB Cluster programs

Format	Description	Added, Deprecated, or Removed
`--character-sets-dir=dir_name`	Directory where character sets are installed	All NDB 8.0 releases
`--connect-retries=#`	Set the number of times to retry a connection before giving up	All NDB 8.0 releases
`--connect-retry-delay=#`	Time to wait between attempts to contact a management server, in seconds	All NDB 8.0 releases
`--core-file`	Write core on errors (defaults to TRUE in debug builds)	All NDB 8.0 releases
`--debug=options`	Enable output from debug calls. Can be used only for versions compiled with debugging enabled	All NDB 8.0 releases
`--defaults-extra-file=filename`	Read this file after global option files are read	All NDB 8.0 releases
`--defaults-file=filename`	Read default options from this file	All NDB 8.0 releases
`--defaults-group-suffix`	Also read groups with names ending in this suffix	All NDB 8.0 releases
`--help`, `--usage`, `-?`	Display help message and exit	All NDB 8.0 releases
`--login-path=path`	Read this path from the login file	All NDB 8.0 releases

Format	Description	Added, Deprecated, or Removed
`--ndb-connectstring=connectstring`, `--connect-string=connectstring`, `-c`	Set connection string for connecting to ndb_mgmd. Syntax: [nodeid=<id>;] [host=]<hostname>[:<port>]. Overrides entries specified in NDB_CONNECTSTRING or my.cnf.	All NDB 8.0 releases
`--ndb-mgmd-host=host[:port]`	Set the host (and port, if desired) for connecting to management server	All NDB 8.0 releases
`--ndb-nodeid=#`	Set node id for this node	All NDB 8.0 releases
`--ndb-optimized-node-selection`	Select nodes for transactions in a more optimal way	All NDB 8.0 releases
`--no-defaults`	Do not read default options from any option file other than login file	All NDB 8.0 releases
`--print-defaults`	Print the program argument list and exit	All NDB 8.0 releases
`--version`, `-V`	Output version information and exit	All NDB 8.0 releases

For options specific to individual NDB Cluster programs, see Section 22.4, “NDB Cluster Programs”.

See MySQL Server Options for NDB Cluster, for `mysqld` options relating to NDB Cluster.

- `--character-sets-dir=name`

Property	Value
Command-Line Format	`--character-sets-dir=dir_name`
Type	Directory name
Default Value	

Tells the program where to find character set information.

- `--connect-retries=#`

Property	Value
Command-Line Format	`--connect-retries=#`
Type	Numeric
Default Value	`12`
Minimum Value	`0`
Maximum Value	`4294967295`

This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using `--connect-retry-delay`.

Note

When used with `ndb_mgm`, this option has 3 as its default. See Section 22.4.5, “`ndb_mgm` — The NDB Cluster Management Client”, for more information.

- `--connect-retry-delay=#`

Property	Value
Command-Line Format	`--connect-retry-delay=#`
Type	Numeric
Default Value	`5`
Minimum Value	`1`
Minimum Value	`0`
Maximum Value	`4294967295`

This option specifies the length of time to wait per attempt a connection before giving up. The number of times to try connecting is set by `--connect-retries`.

- `--core-file`

Property	Value
Command-Line Format	`--core-file`
Type	Boolean
Default Value	`FALSE`

Write a core file if the program dies. The name and location of the core file are system-dependent. (For NDB Cluster programs nodes running on Linux, the default location is the program's working directory—for a data node, this is the node's `DataDir`.) For some systems, there may be restrictions or limitations; for example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation for detailed information.

If NDB Cluster was built using the `--debug` option for `configure`, then `--core-file` is enabled by default. For regular builds, `--core-file` is disabled by default.

- `--debug[=options]`

Property	Value
Command-Line Format	`--debug=options`
Type	String
Default Value	`d:t:O,/tmp/ndb_restore.trace`

This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- `--defaults-extra-file=filename`

Property	Value
Command-Line Format	`--defaults-extra-file=filename`
Type	String
Default Value	`[none]`

Read this file after global option files are read.

For additional information about this and other option-file options, see Section 4.2.8, “Command-Line Options that Affect Option-File Handling”.

- `--defaults-file=filename`

Property	Value
Command-Line Format	`--defaults-file=filename`
Type	String
Default Value	`[none]`

Read default options from this file.

For additional information about this and other option-file options, see Section 4.2.8, “Command-Line Options that Affect Option-File Handling”.

- `--defaults-group-suffix`

Property	Value
Command-Line Format	`--defaults-group-suffix`
Type	String
Default Value	`[none]`

Also read groups with names ending in this suffix.

For additional information about this and other option-file options, see Section 4.2.8, “Command-Line Options that Affect Option-File Handling”.

- `--help`, `--usage`, `-?`

Property	Value

Command-Line Format	`--help`
	
	`--usage`

Prints a short list with descriptions of the available command options.

- `--login-path=`*`path`*

Property	Value
Command-Line Format	`--login-path=path`
Type	String
Default Value	`[none]`

Read this path from the login file.

For additional information about this and other option-file options, see Section 4.2.8, “Command-Line Options that Affect Option-File Handling”.

- `--ndb-connectstring=`*`connection_string`*, `--connect-string=`*`connection_string`*, `-c` *`connection_string`*

Property	Value

Command-Line Format	`--ndb-connectstring=connectstring`
	
	`--connect-string=connectstring`

Type	String
Default Value	`localhost:1186`

This option takes an NDB Cluster connection string that specifies the management server for the application to connect to, as shown here:

```
shell> ndbd --ndb-connectstring="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

For more information, see Section 22.3.3.3, “NDB Cluster Connection Strings”.

- `--ndb-mgmd-host=host[:port]`

Property	Value
Command-Line Format	`--ndb-mgmd-host=host[:port]`
Type	String
Default Value	`localhost:1186`

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=#`

Property	Value
Command-Line Format	`--ndb-nodeid=#`
Type	Numeric
Default Value	`0`

Sets this node's NDB Cluster node ID. *The range of permitted values depends on the node's type (data, management, or API) and the NDB Cluster software version*. See Section 22.1.7.2, “Limits and Differences of NDB Cluster from Standard MySQL Limits”, for more information.

- `--no-defaults`

Property	Value
Command-Line Format	`--no-defaults`
Type	Boolean
Default Value	`TRUE`

Do not read default options from any option file other than login file.

For additional information about this and other option-file options, see Section 4.2.8, “Command-Line Options that Affect Option-File Handling”.

- `--ndb-optimized-node-selection`

Property	Value
Command-Line Format	`--ndb-optimized-node-selection`
Type	Boolean
Default Value	`TRUE`

Optimize selection of nodes for transactions. Enabled by default.

- `--print-defaults`

Property	Value
Command-Line Format	`--print-defaults`
Type	Boolean
Default Value	`TRUE`

Print the program argument list and exit.

For additional information about this and other option-file options, see Section 4.2.8, “Command-Line Options that Affect Option-File Handling”.

- `--version`, `-V`

Property	Value
Command-Line Format	`--version`

Prints the NDB Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the NDB Cluster startup process verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of NDB Cluster.

See Section 22.5.5, “Performing a Rolling Restart of an NDB Cluster”), for more information.

22.5 Management of NDB Cluster

Managing an NDB Cluster involves a number of tasks, the first of which is to configure and start NDB Cluster. This is covered in Section 22.3, “Configuration of NDB Cluster”, and Section 22.4, “NDB Cluster Programs”.

The next few sections cover the management of a running NDB Cluster.

For information about security issues relating to management and deployment of an NDB Cluster, see Section 22.5.12, “NDB Cluster Security Issues”.

There are essentially two methods of actively managing a running NDB Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_`*`node_id`*`_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option. (Recall that *`node_id`* represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can be also be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement.

More detailed information about NDB Cluster operations is available in real time through an SQL interface using the `ndbinfo` database. For more information, see Section 22.5.10, “ndbinfo: The NDB Cluster Information Database”.

NDB statistics counters provide improved monitoring using the `mysql` client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting `Ndb` objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by NDB Cluster. The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

`mysqld` exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (`Ndb_api_`). The values of these variables can be

read in the `mysql` client from the output of a `SHOW STATUS` statement, or by querying either the `SESSION_STATUS` table or the `GLOBAL_STATUS` table (in the `INFORMATION_SCHEMA` database). By comparing the values of the status variables before and after the execution of an SQL statement that acts on `NDB` tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of NDB Cluster.

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex NDB Cluster management tasks, such as starting, stopping, or restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to NDB Cluster. See MySQL™ Cluster Manager 1.4.7 User Manual, for more information.

22.5.1 Summary of NDB Cluster Start Phases

This section provides a simplified outline of the steps involved when NDB Cluster data nodes are started. More complete information can be found in NDB Cluster Start Phases, in the *NDB Internals Guide*.

These phases are the same as those reported in the output from the *`node_id`* `STATUS` command in the management client (see Section 22.5.2, “Commands in the NDB Cluster Management Client”). These start phases are also reported in the `start_phase` column of the `ndbinfo.nodes` table.

Start types. There are several different startup types and modes, as shown in the following list:

- **Initial start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.

  Note

  Disk Data files are not removed when restarting a node using `--initial`.

- **System restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.

- **Node restart.** This is the online restart of a cluster node while the cluster itself is running.

- **Initial node restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

Setup and initialization (phase -1). Prior to startup, each data node (`ndbd` process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one `ndbd` reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and `ndb_mgmd`.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The NDBFS and NDBCNTR blocks start (see NDB Kernel Blocks). Data node file systems are cleared on those data nodes that were started with `--initial` option.
- **Phase 1.** In this stage, all remaining NDB kernel blocks are started. NDB Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

  Note

  When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.
- **Phase 2.** The NDBCNTR kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.
- **Phase 3.** The DBLQH and DBTC kernel blocks set up communications between them. The startup type is determined; if this is a restart, the DBDIH block obtains permission to perform the restart.
- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFiles`.

  For a system restart:

  - Read schema or schemas.
  - Read data from the local checkpoint.
  - Apply all redo information until the latest restorable global checkpoint has been reached.

  For a node restart, find the tail of the redo log.
- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.
- **Phase 6.** In this phase, node groups are defined and set up.
- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as `Started`. It is now possible for API nodes (including SQL nodes) to connect to the cluster.
- **Phase 8.** If this is a system restart, all indexes are rebuilt (by DBDIH).
- **Phase 9.** The node internal startup variables are reset.
- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.
- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as *SUMA handover phase*.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

22.5.2 Commands in the NDB Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in Section 22.5.6, “Event Reports Generated in NDB Cluster”; commands for creating backups and restoring from them are provided in Section 22.5.3, “Online Backup of NDB Cluster”.

Using ndb_mgm with MySQL Cluster Manager. MySQL Cluster Manager handles starting and stopping processes and tracks their states internally, so it is not necessary to use `ndb_mgm` for these tasks for an NDB Cluster that is under MySQL Cluster Manager control. it is recommended *not* to use the `ndb_mgm` command-line client that comes with the NDB Cluster distribution to perform operations that involve starting or stopping nodes. These include but are not limited to the `START`, `STOP`, `RESTART`, and `SHUTDOWN` commands. For more information, see MySQL Cluster Manager Process Commands.

The management client has the following basic commands. In the listing that follows, *`node_id`* denotes either a data node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `HELP`

  Displays information on all available commands.

- `CONNECT` *`connection-string`*

  Connects to the management server indicated by the connection string. If the client is already connected to this server, the client reconnects.

- `SHOW`

  Displays information on the cluster's status. Possible node status values include `UNKNOWN`, `NO_CONTACT`, `NOT_STARTED`, `STARTING`, `STARTED`, `SHUTTING_DOWN`, and `RESTARTING`. The output from this command also indicates when the cluster is in single user mode (status `SINGLE USER MODE`).

- *`node_id`* `START`

  Brings online the data node identified by *`node_id`* (or all data nodes).

  `ALL START` works on all data nodes only, and does not affect management nodes.

  Important

  To use this command to bring a data node online, the data node must have been started using `--nostart` or `-n`.

- *`node_id`* `STOP [-a] [-f]`

  Stops the data or management node identified by *`node_id`*.

  Note

  `ALL STOP` works to stop all data nodes only, and does not affect management nodes.

  A node affected by this command disconnects from the cluster, and its associated `ndbd` or `ndb_mgmd` process terminates.

  The `-a` option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

Normally, STOP fails if the result would cause an incomplete cluster. The -f option forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

Warning

Use of the -a option also disables the safety check otherwise performed when STOP is invoked to insure that stopping the node does not cause an incomplete cluster. In other words, you should exercise extreme care when using the -a option with the STOP command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in NDB.

- *node_id* RESTART [-n] [-i] [-a] [-f]

  Restarts the data node identified by *node_id* (or all data nodes).

  Using the -i option with RESTART causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using ndbd --initial from the system shell.

  Note

  Backup files and Disk Data files are not removed when this option is used.

  Using the -n option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate START command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using ndbd --nostart or ndbd -n from the system shell.

  Using the -a causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

  Normally, RESTART fails if taking the node offline would result in an incomplete cluster. The -f option forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

- *node_id* STATUS

  Displays status information for the data node identified by *node_id* (or for all data nodes).

  The output from this command also indicates when the cluster is in single user mode.

- *node_id* REPORT *report-type*

  Displays a report of type *report-type* for the data node identified by *node_id*, or for all data nodes using ALL.

  Currently, there are three accepted values for *report-type*:

  - BackupStatus provides a status report on a cluster backup in progress
  - MemoryUsage displays how much data memory and index memory is being used by each data node as shown in this example:

    ```
    ndb_mgm> ALL REPORT MEMORY

    Node 1: Data usage is 5%(177 32K pages of total 3200)
    Node 1: Index usage is 0%(108 8K pages of total 12832)
    Node 2: Data usage is 5%(177 32K pages of total 3200)
    ```

```
Node 2: Index usage is 0%(108 8K pages of total 12832)
```

This information is also available from the `ndbinfo.memoryusage` table.

- `EventLog` reports events from the event log buffers of one or more data nodes.

`report-type` is case-insensitive and “fuzzy”; for `MemoryUsage`, you can use `MEMORY` (as shown in the prior example), `memory`, or even simply `MEM` (or `mem`). You can abbreviate `BackupStatus` in a similar fashion.

- `ENTER SINGLE USER MODE` *`node_id`*

  Enters single user mode, whereby only the MySQL server identified by the node ID *`node_id`* is permitted to access the database.

  Currently, it is not possible for data nodes to join an NDB Cluster while it is running in single user mode. (Bug #20395)

- `EXIT SINGLE USER MODE`

  Exits single user mode, enabling all SQL nodes (that is, all running `mysqld` processes) to access the database.

  Note

  It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no effect in this case.

- `QUIT`, `EXIT`

  Terminates the management client.

  This command does not affect any nodes connected to the cluster.

- `SHUTDOWN`

  Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

  This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

- `CREATE NODEGROUP` *`nodeid`*`[, nodeid, ...]`

  Creates a new NDB Cluster node group and causes data nodes to join it.

  This command is used after adding new data nodes online to an NDB Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started that are to join the new node group. The number of nodes must be the same as the number of nodes in each node group that is already part of the cluster (each NDB Cluster node group must have the same number of nodes). In other words, if the NDB Cluster has 2 node groups of 2 data nodes each, then the new node group must also have 2 data nodes.

  The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

  For more information, see Section 22.5.15, “Adding NDB Cluster Data Nodes Online”.

- `DROP NODEGROUP` *`nodegroup_id`*

  Drops the NDB Cluster node group with the given *`nodegroup_id`*.

This command can be used to drop a node group from an NDB Cluster. `DROP NODEGROUP` takes as its sole argument the node group ID of the node group to be dropped.

`DROP NODEGROUP` acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster's configuration. A data node that does not belong to a node group is indicated in the output of the management client `SHOW` command with `no nodegroup` in place of the node group ID, like this (indicated using bold text):

```
id=3    @10.100.2.67  (8.0.16-ndb-8.0.16, no nodegroup)
```

`DROP NODEGROUP` works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using `ndb_mgm` or the `mysql` client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.

2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

   `TRUNCATE TABLE` does not work for this purpose because this removes only the table data; the data nodes continue to store an `NDBCLUSTER` table's definition until a `DROP TABLE` statement is issued that causes the table metadata to be dropped.

For more information about `DROP NODEGROUP`, see Section 22.5.15, “Adding NDB Cluster Data Nodes Online”.

- `PROMPT [`*`prompt`*`]`

  Changes the prompt shown by `ndb_mgm` to the string literal *`prompt`*.

  `prompt` should not be quoted (unless you want the prompt to include the quotation marks). Unlike the case with the `mysql` client, special character sequences and escapes are not recognized. If called without an argument, the command resets the prompt to the default value (`ndb_mgm>`).

  Some examples are shown here:

  ```
  ndb_mgm> PROMPT mgm#1:
  mgm#1: SHOW
  Cluster Configuration
  ...
  mgm#1: PROMPT mymgm >
  mymgm > PROMPT 'mymgm:'
  'mymgm:' PROMPT  mymgm:
  mymgm: PROMPT
  ndb_mgm> EXIT
  jon@valhaj:~/bin>
  ```

  Note that leading spaces and spaces within the *`prompt`* string are not trimmed. Trailing spaces are removed.

- *`node_id`* `NODELOG DEBUG {ON|OFF}`

  Toggles debug logging in the node log, as though the effected data node or nodes had been started with the `--verbose` option. `NODELOG DEBUG ON` starts debug logging; `NODELOG DEBUG OFF` switches debug logging off.

Additional commands. A number of other commands available in the `ndb_mgm` client are described elsewhere, as shown in the following list:

- `START BACKUP` is used to perform an online backup in the `ndb_mgm` client; the `ABORT BACKUP` command is used to cancel a backup already in progress. For more information, see Section 22.5.3, “Online Backup of NDB Cluster”.
- The `CLUSTERLOG` command is used to perform various logging functions. See Section 22.5.6, “Event Reports Generated in NDB Cluster”, for more information and examples. `NODELOG DEBUG` activates or deactivates debug printouts in node logs, as described previously in this section.
- For testing and diagnostics work, the client supports a `DUMP` command which can be used to execute internal commands on the cluster. It should never be used in a production setting unless directed to do so by MySQL Support. For more information, see MySQL NDB Cluster Internals Manual.

22.5.3 Online Backup of NDB Cluster

The next few sections describe how to prepare for and then to create an NDB Cluster backup using the functionality for this purpose found in the `ndb_mgm` management client. To distinguish this type of backup from a backup made using `mysqldump`, we sometimes refer to it as a “native” NDB Cluster backup. (For information about the creation of backups with `mysqldump`, see Section 4.5.4, “`mysqldump` — A Database Backup Program”.) Restoration of NDB Cluster backups is done using the `ndb_restore` utility provided with the NDB Cluster distribution; for information about `ndb_restore` and its use in restoring NDB Cluster backups, see Section 22.4.23, “`ndb_restore` — Restore an NDB Cluster Backup”.

22.5.3.1 NDB Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-`*`backup_id`*`.`*`node_id`*`.ctl`

  A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-`*`backup_id`*`-0.`*`node_id`*`.data`

  A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-`*`backup_id`*`.`*`node_id`*`.log`

  A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing just shown, *`backup_id`* stands for the backup identifier and *`node_id`* is the unique identifier for the node creating the file.

The location of the backup files is determined by the `BackupDataDir` parameter.

22.5.3.2 Using The NDB Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See Section 22.5.3.3, “Configuration for NDB Cluster Backups”.)

The START BACKUP command is used to create a backup:

```
START BACKUP [backup_id] [wait_option] [snapshot_option]

wait_option:
WAIT {STARTED | COMPLETED} | NOWAIT

snapshot_option:
SNAPSHOTSTART | SNAPSHOTEND
```

Successive backups are automatically identified sequentially, so the *backup_id*, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing *backup_id* value is used, the backup fails with the error Backup failed: file already exists. If used, the *backup_id* must follow START BACKUP immediately, before any other options are used.

The *wait_option* can be used to determine when control is returned to the management client after a START BACKUP command is issued, as shown in the following list:

- If NOWAIT is specified, the management client displays a prompt immediately, as seen here:

  ```
  ndb_mgm> START BACKUP NOWAIT
  ndb_mgm>
  ```

  In this case, the management client can be used even while it prints progress information from the backup process.

- With WAIT STARTED the management client waits until the backup has started before returning control to the user, as shown here:

  ```
  ndb_mgm> START BACKUP WAIT STARTED
  Waiting for started, this may take several minutes
  Node 2: Backup 3 started from node 1
  ndb_mgm>
  ```

- **WAIT COMPLETED** causes the management client to wait until the backup process is complete before returning control to the user.

WAIT COMPLETED is the default.

A *snapshot_option* can be used to determine whether the backup matches the state of the cluster when START BACKUP was issued, or when it was completed. SNAPSHOTSTART causes the backup to match the state of the cluster when the backup began; SNAPSHOTEND causes the backup to reflect the state of the cluster when the backup was finished. SNAPSHOTEND is the default, and matches the behavior found in previous NDB Cluster releases.

Note

If you use the SNAPSHOTSTART option with START BACKUP, and the CompressedBackup parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a *wait_option* and a *snapshot_option* are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
START BACKUP SNAPSHOTSTART WAIT STARTED
START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
START BACKUP SNAPSHOTEND WAIT COMPLETED
START BACKUP 4 NOWAIT SNAPSHOTSTART
```

The procedure for creating a backup consists of the following steps:

1. Start the management client (`ndb_mgm`), if it not running already.

2. Execute the **START BACKUP** command. This produces several lines of output indicating the progress of the backup, as shown here:

```
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 2: Backup 1 started from node 1
Node 2: Backup 1 started from node 1 completed
 StartGCP: 177 StopGCP: 180
 #Records: 7362 #LogRecords: 0
 Data: 453648 bytes Log: 0 bytes
ndb_mgm>
```

3. When the backup has started the management client displays this message:

```
Backup backup_id started from node node_id
```

   `backup_id` is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. *`node_id`* is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

```
Node 2: Backup 1 started from node 1
```

4. The management client indicates with a message like this one that the backup has started:

```
Backup backup_id started from node node_id completed
```

   As is the case for the notification that the backup has started, *`backup_id`* is the unique identifier for this particular backup, and *`node_id`* is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```
Node 2: Backup 1 started from node 1 completed
 StartGCP: 177 StopGCP: 180
 #Records: 7362 #LogRecords: 0
 Data: 453648 bytes Log: 0 bytes
```

It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` option, as shown in this example:

```
shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using `START BACKUP` in this way, you must specify the backup ID.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter. The backup files created for a backup with a given *`backup_id`* are stored in a subdirectory named `BACKUP-`*`backup_id`* in the backup directory.

Cancelling backups. To cancel or abort a backup that is already in progress, perform the following steps:

1. Start the management client.

2. Execute this command:

```
ndb_mgm> ABORT BACKUP backup_id
```

   The number *`backup_id`* is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

3. The management client will acknowledge the abort request with `Abort of backup backup_id ordered`.

Note

At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client will report this fact in a manner similar to what is shown here:

```
Node 1: Backup 3 started from 5 has been aborted.
  Error: 1321 - Backup aborted by user request: Permanent error: User defined error
Node 3: Backup 3 started from 5 has been aborted.
  Error: 1323 - 1323: Permanent error: Internal error
Node 2: Backup 3 started from 5 has been aborted.
  Error: 1323 - 1323: Permanent error: Internal error
Node 4: Backup 3 started from 5 has been aborted.
  Error: 1323 - 1323: Permanent error: Internal error
```

   In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

Note

There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

   The `Backup backup_id started from node management_node_id has been aborted` messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

Note

If there is no backup having the ID *`backup_id`* running when an `ABORT BACKUP` is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

22.5.3.3 Configuration for NDB Cluster Backups

Five configuration parameters are essential for backup:

- `BackupDataBufferSize`

  The amount of memory used to buffer data before it is written to disk.

- `BackupLogBufferSize`

  The amount of memory used to buffer log records before these are written to disk.

- `BackupMemory`

  The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- `BackupWriteSize`

  The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- `BackupMaxWriteSize`

  The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in Backup Parameters.

You can also set a location for the backup files using the `BackupDataDir` configuration parameter. The default is `FileSystemPath/BACKUP/BACKUP-`*`backup_id`*.

22.5.3.4 NDB Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

Important

If you have set `BackupDataBufferSize` and `BackupLogBufferSize` and their sum is greater than 4MB, then you must also set `BackupMemory` as well.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

`NDB` does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring an NDB Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

22.5.4 MySQL Server Usage for NDB Cluster

`mysqld` is the traditional MySQL server process. To be used with NDB Cluster, `mysqld` needs to be built with support for the `NDB` storage engine, as it is in the precompiled binaries available from https://dev.mysql.com/downloads/. If you build MySQL from source, you must invoke `CMake` with the `-DWITH_NDBCLUSTER=1` option to include support for `NDB`.

For more information about compiling NDB Cluster from source, see Section 22.2.2.4, “Building NDB Cluster from Source on Linux”, and Section 22.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”.

(For information about `mysqld` options and variables, in addition to those discussed in this section, which are relevant to NDB Cluster, see Section 22.3.3.9, “MySQL Server Options and Variables for NDB Cluster”.)

If the `mysqld` binary has been built with Cluster support, the `NDBCLUSTER` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.

- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDBCLUSTER` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an `NDB`-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server (MGM node)
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connection string either on the command line when starting `mysqld` or in `my.cnf`. The connection string contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See Section 22.3.3.3, “NDB Cluster Connection Strings”, for more information on connection strings.

Given this information, the MySQL server will be a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
*************************** 1. row ***************************
     Id: 1
   User: system user
   Host:
     db:
Command: Daemon
   Time: 1
  State: Waiting for event from ndbcluster
   Info: NULL
```

Important

To participate in an NDB Cluster, the `mysqld` process must be started with *both* the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with `NDB` tables, *nor is it possible to create any new tables regardless of storage engine*. The latter restriction is a safety measure intended to prevent the creation of tables having the same names as `NDB` tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in an NDB Cluster, you must restart the server *without* the `--ndbcluster` option.

22.5.5 Performing a Rolling Restart of an NDB Cluster

This section discusses how to perform a *rolling restart* of an NDB Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

Configuration change.
To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

NDB Cluster software upgrade or downgrade. To upgrade the cluster to a newer version of the NDB Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of NDB Cluster).

Change on node host. To make changes in the hardware or operating system on which one or more NDB Cluster node processes are running.

System reset (cluster reset).
To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

- Start each data node process (`ndbd` or possibly `ndbmtd`) with the `--initial` option, which forces the data node to clear its file system and to reload all NDB Cluster data and metadata from the other data nodes.
- Create a backup using the `ndb_mgm` client `START BACKUP` command prior to performing the restart. Following the upgrade, restore the node or nodes using `ndb_restore`.

  See Section 22.5.3, “Online Backup of NDB Cluster”, and Section 22.4.23, “`ndb_restore` — Restore an NDB Cluster Backup”, for more information.
- Use `mysqldump` to create a backup prior to the upgrade; afterward, restore the dump using `LOAD DATA`.

Resource Recovery.
To free memory previously allocated to a table by successive `INSERT` and `DELETE` operations, for re-use by other NDB Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them. (See Rolling restarts with multiple management servers.)
2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn.

   Some node configuration parameters can be updated by issuing `RESTART` for each of the data nodes in the `ndb_mgm` client following the previous step; others require that the data node be stopped completely using a shell command (such as `kill` on most Unix systems) or the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndbmtd` executable as appropriate.

Note

On Windows, you can also use `SC STOP` and `SC START` commands, `NET STOP` and `NET START` commands, or the Windows Service Manager to

stop and start nodes which have been installed as Windows services (see Section 22.2.3.4, “Installing NDB Cluster Processes as Windows Services”).

The type of restart required is indicated in the documentation for each node configuration parameter. See Section 22.3.3, “NDB Cluster Configuration Files”.

3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn.

NDB Cluster supports a somewhat flexible order for upgrading nodes. When upgrading an NDB Cluster, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different NDB Cluster releases is neither intended nor supported for continuous, long-term use in a production setting.
- All management nodes must be upgraded before any data nodes are upgraded. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.
- Features specific to the “new” version must not be used until all management nodes and data nodes have been upgraded.

  This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of NDB Cluster in general.)

See also Bug #48528 and Bug #49163.

Note

It is not possible for any API node to perform schema operations (such as data definition statements) during a node restart.

Rolling restarts with multiple management servers. When performing a rolling restart of an NDB Cluster with multiple management nodes, you should keep in mind that `ndb_mgmd` checks to see if any other management node is running, and, if so, tries to use that node's configuration data. To keep this from occurring, and to force `ndb_mgmd` to reread its configuration file, perform the following steps:

1. Stop all NDB Cluster `ndb_mgmd` processes.
2. Update all `config.ini` files.
3. Start a single `ndb_mgmd` with `--reload`, `--initial`, or both options as desired.
4. If you started the first `ndb_mgmd` with the `--initial` option, you must also start any remaining `ndb_mgmd` processes using `--initial`.

   Regardless of any other options used when starting the first `ndb_mgmd`, you should not start any remaining `ndb_mgmd` processes after the first one using `--reload`.
5. Complete the rolling restarts of the data nodes and API nodes as normal.

When performing a rolling restart to update the cluster's configuration, you can use the `config_generation` column of the `ndbinfo.nodes` table to keep track of which data nodes have been successfully restarted with the new configuration. See Section 22.5.10.28, “The ndbinfo nodes Table”.

22.5.6 Event Reports Generated in NDB Cluster

In this section, we discuss the types of event logs provided by NDB Cluster, and the types of events that are logged.

NDB Cluster provides two types of event log:

- The *cluster log*, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

  By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where *`node_id`* is the node ID of the management server) in the management server's `DataDir`.

  Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See Section 22.3.3.5, “Defining an NDB Cluster Management Server”, for more information about these parameters.

- *Node logs* are local to each node.

  Output generated by node event logging is written to the file `ndb_node_id_out.log` (where *`node_id`* is the node's node ID) in the node's `DataDir`. Node event logs are generated for both management nodes and data nodes.

  Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- *Category*: This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERESTART`, `CONNECTION`, `ERROR`, or `INFO`.
- *Priority*: This is represented by one of the numbers from 0 to 15 inclusive, where 0 indicates “most important” and 15 “least important.”
- *Severity Level*: This can be any one of the following values: `ALERT`, `CRITICAL`, `ERROR`, `WARNING`, `INFO`, or `DEBUG`.

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

```
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 1: Data usage is 2%(60 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 1: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 1: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 2: Data usage is 2%(76 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 2: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 2: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 3: Data usage is 2%(58 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 3: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 3: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 4: Data usage is 2%(74 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 4: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 4: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 4: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 1: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 1: Node 9: API 8.0.16-ndb-8.0.16
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 2: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 2: Node 9: API 8.0.16-ndb-8.0.16
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 3: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 3: Node 9: API 8.0.16-ndb-8.0.16
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 4: Node 9: API 8.0.16-ndb-8.0.16
2007-01-26 19:59:22 [MgmSrvr] ALERT    -- Node 2: Node 7 Disconnected
2007-01-26 19:59:22 [MgmSrvr] ALERT    -- Node 2: Node 7 Disconnected
```

Each line in the cluster log contains the following information:

- A timestamp in *YYYY-MM-DD HH:MM:SS* format.
- The type of node which is performing the logging. In the cluster log, this is always [MgmSrvr].
- The severity of the event.
- The ID of the node reporting the event.
- A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

22.5.6.1 NDB Cluster Logging Management Commands

ndb_mgm supports a number of management commands related to the cluster log and node logs. In the listing that follows, *node_id* denotes either a storage node ID or the keyword ALL, which indicates that the command should be applied to all of the cluster's data nodes.

- CLUSTERLOG ON

  Turns the cluster log on.

- CLUSTERLOG OFF

  Turns the cluster log off.

- CLUSTERLOG INFO

  Provides information about cluster log settings.

- *node_id* CLUSTERLOG *category=threshold*

  Logs *category* events with priority less than or equal to *threshold* in the cluster log.

- CLUSTERLOG FILTER *severity_level*

  Toggles cluster logging of events of the specified *severity_level*.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

Note

Events are reported per data node, and that the threshold can be set to different values on different nodes.

Table 22.350 Cluster log categories, with default threshold setting

Category	Default threshold (All data nodes)
STARTUP	**7**
SHUTDOWN	**7**
STATISTICS	**7**
CHECKPOINT	**7**
NODERESTART	**7**
CONNECTION	**7**
ERROR	**15**
INFO	**7**

The STATISTICS category can provide a great deal of useful data. See Section 22.5.6.3, “Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client”, for more information.

Thresholds are used to filter events within each category. For example, a STARTUP event with a priority of 3 is not logged unless the threshold for STARTUP is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

Note

These correspond to Unix syslog levels, except for LOG_EMERG and LOG_NOTICE, which are not used or mapped.

Table 22.351 Event severity levels

Severity Level Value	Severity	Description
1	ALERT	A condition that should be corrected immediately, such as a corrupted system database
2	CRITICAL	Critical conditions, such as device errors or insufficient resources
3	ERROR	Conditions that should be corrected, such as configuration errors
4	WARNING	Conditions that are not errors, but that might require special handling
5	INFO	Informational messages
6	DEBUG	Debugging messages used for NDBCLUSTER development

Event severity levels can be turned on or off (using CLUSTERLOG FILTER—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

Important

Cluster log levels are set on a per ndb_mgmd, per subscriber basis. This means that, in an NDB Cluster with multiple management servers, using a CLUSTERLOG command in an instance of ndb_mgm connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

22.5.6.2 NDB Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

CONNECTION Events

These events are associated with connections between Cluster nodes.

Table 22.352 Events associated with connections between cluster nodes

Event	Priority	Severity Level	Description
Connected	8	INFO	Data nodes connected
Disconnected	8	ALERT	Data nodes disconnected
CommunicationClosed	8	INFO	SQL node or data node connection closed
CommunicationOpened	8	INFO	SQL node or data node connection open
ConnectedApiVersion	8	INFO	Connection using API version

CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

Table 22.353 Events associated with checkpoints

Event	Priority	Severity Level	Description
GlobalCheckpointStarted	9	INFO	Start of GCP: REDO log is written to disk
GlobalCheckpointCompleted	10	INFO	GCP finished
LocalCheckpointStarted	7	INFO	Start of LCP: data written to disk
LocalCheckpointCompleted	7	INFO	LCP completed normally
LCPStoppedInCalcKeepGci	0	ALERT	LCP stopped
LCPFragmentCompleted	11	INFO	LCP on a fragment has been completed
UndoLogBlocked	7	INFO	UNDO logging blocked; buffer near overflow
RedoStatus	7	INFO	Redo status

STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

Table 22.354 Events relating to the startup of a node or cluster

Event	Priority	Severity Level	Description
NDBStartStarted	1	INFO	Data node start phases initiated (all nodes starting)
NDBStartCompleted	1	INFO	Start phases completed, all data nodes
STTORRYRecieved	15	INFO	Blocks received after completion of restart
StartPhaseCompleted	4	INFO	Data node start phase *X* completed
CM_REGCONF	3	INFO	Node has been successfully included into the cluster; shows the node, managing node, and dynamic ID
CM_REGREF	8	INFO	Node has been refused for inclusion in the cluster; cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem

Event	Priority	Severity Level	Description
FIND_NEIGHBOURS	8	INFO	Shows neighboring data nodes
NDBStopStarted	1	INFO	Data node shutdown initiated
NDBStopCompleted	1	INFO	Data node shutdown complete
NDBStopForced	1	ALERT	Forced shutdown of data node
NDBStopAborted	1	INFO	Unable to shut down data node normally
StartREDOLog	4	INFO	New redo log started; GCI keep *X*, newest restorable GCI *Y*
StartLog	10	INFO	New log started; log part *X*, start MB *Y*, stop MB *Z*
UNDORecordsExecuted	15	INFO	Undo records executed
StartReport	4	INFO	Report started
LogFileInitStatus	7	INFO	Log file initialization status
LogFileInitCompStatus	7	INFO	Log file completion status
StartReadLCP	10	INFO	Start read for local checkpoint
ReadLCPComplete	10	INFO	Read for local checkpoint completed
RunRedo	8	INFO	Running the redo log
RebuildIndex	10	INFO	Rebuilding indexes

NODERESTART Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

Table 22.355 Events relating to restarting a node

Event	Priority	Severity Level	Description
NR_CopyDict	7	INFO	Completed copying of dictionary information
NR_CopyDistr	7	INFO	Completed copying distribution information
NR_CopyFragsStarted	7	INFO	Starting to copy fragments
NR_CopyFragDone	10	INFO	Completed copying a fragment
NR_CopyFragsCompleted	7	INFO	Completed copying all fragments
NodeFailCompleted	8	ALERT	Node failure phase completed
NODE_FAILREP	8	ALERT	Reports that a node has failed
ArbitState	6	INFO	Report whether an arbitrator is found or not; there are seven different possible outcomes when seeking an arbitrator, listed here: • Management server restarts arbitration thread [state=*X*] • Prepare arbitrator node *X* [ticket=*Y*] • Receive arbitrator node *X* [ticket=*Y*] • Started arbitrator node *X* [ticket=*Y*] • Lost arbitrator node *X* - process failure [state=*Y*]

Event	Priority	Severity Level	Description
			• Lost arbitrator node *X* - process exit [state=*Y*] • Lost arbitrator node *X* <error msg> [state=*Y*]
ArbitResult	2	ALERT	Report arbitrator results; there are eight different possible results for arbitration attempts, listed here: • Arbitration check failed: less than 1/2 nodes left • Arbitration check succeeded: node group majority • Arbitration check failed: missing node group • Network partitioning: arbitration required • Arbitration succeeded: affirmative response from node *X* • Arbitration failed: negative response from node *X* • Network partitioning: no arbitrator available • Network partitioning: no arbitrator configured
GCP_TakeoverStarted	7	INFO	GCP takeover started
GCP_TakeoverCompleted	7	INFO	GCP takeover complete
LCP_TakeoverStarted	7	INFO	LCP takeover started
LCP_TakeoverCompleted	7	INFO	LCP takeover complete (state = *X*)
ConnectCheckStarted	6	INFO	Connection check started
ConnectCheckCompleted	6	INFO	Connection check completed
NodeFailRejected	6	ALERT	Node failure phase failed

STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

Table 22.356 Events of a statistical nature

Event	Priority	Severity Level	Description
TransReportCounters	8	INFO	Report transaction statistics, including numbers of transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts
OperationReportCounters	8	INFO	Number of operations
TableCreated	7	INFO	Report number of tables created

Event	Priority	Severity Level	Description
JobStatistic	9	INFO	Mean internal job scheduling statistics
ThreadConfigLoop	9	INFO	Number of thread configuration loops
SendBytesStatistic	9	INFO	Mean number of bytes sent to node *X*
ReceiveBytesStatistic	9	INFO	Mean number of bytes received from node *X*
MemoryUsage	5	INFO	Data and index memory usage (80%, 90%, and 100%)
MTSignalStatistics	9	INFO	Multithreaded signals

SCHEMA Events

These events relate to NDB Cluster schema operations.

Table 22.357 Events relating to NDB Cluster schema operations

Event	Priority	Severity Level	Description
CreateSchemaObject	8	INFO	Schema objected created
AlterSchemaObject	8	INFO	Schema object updated
DropSchemaObject	8	INFO	Schema object dropped

ERROR Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

Table 22.358 Events relating to cluster errors and warnings

Event	Priority	Severity Level	Description
TransporterError	2	ERROR	Transporter error
TransporterWarning	8	WARNING	Transporter warning
MissedHeartbeat	8	WARNING	Node *X* missed heartbeat number *Y*
DeadDueToHeartbeat	8	ALERT	Node *X* declared “dead” due to missed heartbeat
WarningEvent	2	WARNING	General warning event
SubscriptionStatus	4	WARNING	Change in subscription status

INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

Table 22.359 Information events

Event	Priority	Severity Level	Description
SentHeartbeat	12	INFO	Sent heartbeat
CreateLogBytes	11	INFO	Create log: Log part, log file, size in MB
InfoEvent	2	INFO	General informational event
EventBufferStatus	7	INFO	Event buffer status
EventBufferStatus2	7	INFO	Improved event buffer status information

Note

`SentHeartbeat` events are available only if NDB Cluster was compiled with `VM_TRACE` enabled.

SINGLEUSER Events

These events are associated with entering and exiting single user mode.

Table 22.360 Events relating to single user mode

Event	Priority	Severity Level	Description
`SingleUser`	7	`INFO`	Entering or exiting single user mode

BACKUP Events

These events provide information about backups being created or restored.

Table 22.361 Backup events

Event	Priority	Severity Level	Description
`BackupStarted`	7	`INFO`	Backup started
`BackupStatus`	7	`INFO`	Backup status
`BackupCompleted`	7	`INFO`	Backup completed
`BackupFailedToStart`	7	`ALERT`	Backup failed to start
`BackupAborted`	7	`ALERT`	Backup aborted by user
`RestoreStarted`	7	`INFO`	Started restoring from backup
`RestoreMetaData`	7	`INFO`	Restoring metadata
`RestoreData`	7	`INFO`	Restoring data
`RestoreLog`	7	`INFO`	Restoring log files
`RestoreCompleted`	7	`INFO`	Completed restoring from backup
`SavedEvent`	7	`INFO`	Event saved

22.5.6.3 Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client

The `NDB` management client's `CLUSTERLOG STATISTICS` command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

Transaction coordinator statistics. Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity
- By supplying a data placement hint when the transaction is started

Note

You can determine which TC selection method is used for transactions started from a given SQL node using the `ndb_optimized_node_selection` system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

  Note

  Transactions do not migrate between TCs.

- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for `Commit count` to be greater than `Trans count`.

- **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—1 for the hidden unique index table, and 1 for the table on which the read takes place.

- **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval.

- **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

  Note

  A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

- **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero.

  Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are *not* counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in `AttrInfoCount`.

- **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter.

  The maximum value that `Concurrent Operations` can have is the maximum number of operations that a TC block can support; currently, this is `(2 * MaxNoOfConcurrentOperations) + 16 + MaxNoOfConcurrentTransactions`. (For more information about these configuration parameters, see the *Transaction Parameters* section of Section 22.3.3.6, “Defining NDB Cluster Data Nodes”.)

- **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, `Abort count` can sometimes be greater than `Trans count`.

- **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).
- **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.
- **Local reads.** This is the number of primary-key read operations performed using a transaction coordinator on a node that also holds the primary replica of the record. This count can also be obtained from the `LOCAL_READS` counter in the `ndbinfo.counters` table.
- **Local writes.** This contains the number of primary-key read operations that were performed using a transaction coordinator on a node that also holds the primary replica of the record. This count can also be obtained from the `LOCAL_WRITES` counter in the `ndbinfo.counters` table.

Local query handler statistics (Operations). There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

Note

A single transaction may operate on data stored in multiple LQH blocks.

The `Operations` statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes. For example, in a 2-replica cluster, the write to the primary replica is recorded in the primary LQH, and the write to the backup will be recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does *not* include local operations generated as a result of a table scan or ordered index scan, which are not counted.

Process scheduler statistics. In addition to the statistics reported by the transaction coordinator and local query handler, each `ndbd` process has a scheduler which also provides useful metrics relating to the performance of an NDB Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.
- **Mean send size and Mean receive size.** These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the `NDB` management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

Note

Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the NDB Cluster.

For more information about NDB Cluster management client commands relating to logging and reporting, see Section 22.5.6.1, “NDB Cluster Logging Management Commands”.

22.5.7 NDB Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on `NDB` transporter errors.

22.5.7.1 NDB Cluster: Messages in the Cluster Log

The following table lists the most common `NDB` cluster log messages. For information about the cluster log, log events, and event types, see Section 22.5.6, “Event Reports Generated in NDB Cluster”. These log messages also correspond to log event types in the MGM API; see The Ndb_logevent_type Type, for related information of interest to Cluster API developers.

Table 22.362 Common NDB cluster log messages

Log Message	Description	Event Name	Event Type	Priority	Severity
`Node mgm_node_id: Node data_node_id Connected`	The data node having node ID *`node_id`* has connected to the management server (node *`mgm_node_id`*).	`Connected`	`Connection`	8	`INFO`
`Node mgm_node_id: Node data_node_id Disconnected`	The data node having node ID *`data_node_id`* has disconnected from the management server (node *`mgm_node_id`*).	`Disconnected`	`Connection`	8	`ALERT`
`Node data_node_id: Communication to Node api_node_id closed`	The API node or SQL node having node ID *`api_node_id`* is no longer communicating with data node *`data_node_id`*.	`CommunicationClosed`	`Connection`	8	`INFO`
`Node data_node_id: Communication to Node api_node_id opened`	The API node or SQL node having node ID *`api_node_id`* is now communicating with data node *`data_node_id`*.	`CommunicationOpened`	`Connection`	8	`INFO`
`Node mgm_node_id: Node`	The API node having node ID *`api_node_id`*	`ConnectedApiVersion`	`Connection`	8	`INFO`

Log Message	Description	Event Name	Event Type	Priority	Severity
api_node_id: API *version*	has connected to management node *mgm_node_id* using NDB API version *version* (generally the same as the MySQL version number).				
Node *node_id*: Global checkpoint *gci* started	A global checkpoint with the ID *gci* has been started; node *node_id* is the master responsible for this global checkpoint.	GlobalCheckpointStarted	Checkpoint	9	INFO
Node *node_id*: Global checkpoint *gci* completed	The global checkpoint having the ID *gci* has been completed; node *node_id* was the master responsible for this global checkpoint.	GlobalCheckpointCompleted	Checkpoint	10	INFO
Node *node_id*: Local checkpoint *lcp* started. Keep GCI = *current_gci* oldest restorable GCI = *old_gci*	The local checkpoint having sequence ID *lcp* has been started on node *node_id*. The most recent GCI that can be used has the index *current_gci*, and the oldest GCI from which the cluster can be restored has the index *old_gci*.	LocalCheckpointStarted	Checkpoint	7	INFO
Node *node_id*: Local checkpoint *lcp* completed	The local checkpoint having sequence ID *lcp* on node *node_id* has been completed.	LocalCheckpointCompleted	Checkpoint	8	INFO
Node *node_id*: Local Checkpoint stopped in CALCULATED_KEEP_GCI	The node was unable to determine the most recent usable GCI.	LCPStoppedInCalcKeepGci	Checkpoint	0	ALERT
Node *node_id*: Table ID = *table_id*, fragment *ID* = *fragment_id*	A table fragment has been checkpointed to disk on node *node_id*. The	LCPFragmentCompleted	Checkpoint	11	INFO

Log Message	Description	Event Name	Event Type	Priority	Severity
has completed LCP on Node *node_id* maxGciStarted: *started_gci* maxGciCompleted *completed_gci*	GCI in progress has the index *started_gci*, and the most recent GCI to have been completed has the index *completed_gci*.				
Node *node_id*: ACC Blocked *num_1* and TUP Blocked *num_2* times last second	Undo logging is blocked because the log buffer is close to overflowing.	UndoLogBlocked	Checkpoint	7	INFO
Node *node_id*: Start initiated *version*	Data node *node_id*, running NDB version *version*, is beginning its startup process.	NDBStartStarted	StartUp	1	INFO

22.5.7.2 NDB Cluster Log Startup Messages

Possible startup messages with descriptions are provided in the following list:

- `Initial start, waiting for %s to connect, nodes [ all: %s connected: %s no-wait: %s ]`
- `Waiting until nodes: %s connects, nodes [ all: %s connected: %s no-wait: %s ]`
- `Waiting %u sec for nodes %s to connect, nodes [ all: %s connected: %s no-wait: %s ]`
- `Waiting for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]`
- `Waiting %u sec for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]`
- `Initial start with nodes %s [ missing: %s no-wait: %s ]`
- `Start with all nodes %s`
- `Start with nodes %s [ missing: %s no-wait: %s ]`
- `Start potentially partitioned with nodes %s [ missing: %s no-wait: %s ]`
- `Unknown startreport: 0x%x [ %s %s %s %s ]`

22.5.7.3 Event Buffer Reporting in the Cluster Log

NDB uses one or more memory buffers for events received from the data nodes. There is one such buffer for each Ndb object subscribing to table events, which means that there are usually two buffers for each mysqld performing binary logging (one buffer for schema events, and one for data events). Each buffer contains epochs made up of events. These events consist of operation types (insert, update, delete) and row data (before and after images plus metadata).

NDB generates messages in the cluster log to describe the state of these buffers. Although these reports appear in the cluster log, they refer to buffers on API nodes (unlike most other cluster log messages, which are generated by data nodes).

Event buffer logging reports in the cluster log use the format shown here:

```
Node node_id: Event buffer status (object_id):
used=bytes_used (percent_used% of alloc)
alloc=bytes_allocated (percent_alloc% of max) max=bytes_available
latest_consumed_epoch=latest_consumed_epoch
latest_buffered_epoch=latest_buffered_epoch
report_reason=report_reason
```

The fields making up this report are listed here, with descriptions:

- *`node_id`*: ID of the node where the report originated.
- *`object_id`*: ID of the `Ndb` object where the report originated.
- *`bytes_used`*: Number of bytes used by the buffer.
- *`percent_used`*: Percentage of allocated bytes used.
- *`bytes_allocated`*: Number of bytes allocated to this buffer.
- *`percent_alloc`*: Percentage of available bytes used; not printed if `ndb_eventbuffer_max_alloc` is equal to 0 (unlimited).
- *`bytes_available`*: Number of bytes available; this is 0 if `ndb_eventbuffer_max_alloc` is 0 (unlimited).
- *`latest_consumed_epoch`*: The epoch most recently consumed to completion. (In NDB API applications, this is done by calling `nextEvent()`.)
- *`latest_buffered_epoch`*: The epoch most recently buffered (completely) in the event buffer.
- *`report_reason`*: The reason for making the report. Possible reasons are shown later in this section.

Possible reasons for reporting are described in the following list:

- `ENOUGH_FREE_EVENTBUFFER`: The event buffer has sufficient space.

  `LOW_FREE_EVENTBUFFER`: The event buffer is running low on free space.

  The threshold free percentage level triggering these reports can be adjusted by setting the `ndb_report_thresh_binlog_mem_usage` server variable.

- `BUFFERED_EPOCHS_OVER_THRESHOLD`: Whether the number of buffered epochs has exceeded the configured threshold. This number is the difference between the latest epoch that has been received in its entirety and the epoch that has most recently been consumed (in NDB API applications, this is done by calling `nextEvent()` or `nextEvent2()`). The report is generated every second until the number of buffered epochs goes below the threshold, which can be adjusted by setting the `ndb_report_thresh_binlog_epoch_slip` server variable. You can also adjust the threshold in NDB API applications by calling `setEventBufferQueueEmptyEpoch()`.

- `PARTIALLY_DISCARDING`: Event buffer memory is exhausted—that is, 100% of `ndb_eventbuffer_max_alloc` has been used. Any partially buffered epoch is buffered to completion even is usage exceeds 100%, but any new epochs received are discarded. This means that a gap has occurred in the event stream.

- `COMPLETELY_DISCARDING`: No epochs are buffered.

- `PARTIALLY_BUFFERING`: The buffer free percentage following the gap has risen to the threshold, which can be set in the `mysql` client using the `ndb_eventbuffer_free_percent` server system variable or in NDB API applications by calling `set_eventbuffer_free_percent()`. New epochs are buffered. Epochs that could not be completed due to the gap are discarded.

- `COMPLETELY_BUFFERING`: All epochs received are being buffered, which means that there is sufficient event buffer memory. The gap in the event stream has been closed.

22.5.7.4 NDB Cluster: NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

Table 22.363 Error codes generated by transporter errors

Error Code	Error Name	Error Text
0x00	**TE_NO_ERROR**	No error
0x01	**TE_ERROR_CLOSING_SOCKET**	Error found during closing of socket
0x02	**TE_ERROR_IN_SELECT_BEFORE_ACCEPT**	Error found before accept. The transporter will retry
0x03	**TE_INVALID_MESSAGE_LENGTH**	Error found in message (invalid message length)
0x04	**TE_INVALID_CHECKSUM**	Error found in message (checksum)
0x05	**TE_COULD_NOT_CREATE_SOCKET**	Error found while creating socket(can't create socket)
0x06	**TE_COULD_NOT_BIND_SOCKET**	Error found while binding server socket
0x07	**TE_LISTEN_FAILED**	Error found while listening to server socket
0x08	**TE_ACCEPT_RETURN_ERROR**	Error found during accept(accept return error)
0x0b	**TE_SHM_DISCONNECT**	The remote node has disconnected
0x0c	**TE_SHM_IPC_STAT**	Unable to check shm segment
0x0d	**TE_SHM_UNABLE_TO_CREATE_SEGMENT**	Unable to create shm segment
0x0e	**TE_SHM_UNABLE_TO_ATTACH_SEGMENT**	Unable to attach shm segment
0x0f	**TE_SHM_UNABLE_TO_REMOVE_SEGMENT**	Unable to remove shm segment
0x10	**TE_TOO_SMALL_SIGID**	Sig ID too small
0x11	**TE_TOO_LARGE_SIGID**	Sig ID too large
0x12	**TE_WAIT_STACK_FULL**	Wait stack was full
0x13	**TE_RECEIVE_BUFFER_FULL**	Receive buffer was full
0x14	**TE_SIGNAL_LOST_SEND_BUFFER_FULL**	Send buffer was full,and trying to force send fails

Error Code	Error Name	Error Text
0x15	**TE_SIGNAL_LOST**	Send failed for unknown reason(signal lost)
0x16	**TE_SEND_BUFFER_FULL**	The send buffer was full, but sleeping for a while solved
0x0017	**TE_SCI_LINK_ERROR**	There is no link from this node to the switch
0x18	**TE_SCI_UNABLE_TO_START_SEQUENCE**	Could not start a sequence, because system resources are exumed or no sequence has been created
0x19	**TE_SCI_UNABLE_TO_REMOVE_SEQUENCE**	Could not remove a sequence
0x1a	**TE_SCI_UNABLE_TO_CREATE_SEQUENCE**	Could not create a sequence, because system resources are exempted. Must reboot
0x1b	**TE_SCI_UNRECOVERABLE_DATA_TFX_ERROR**	Tried to send data on redundant link but failed
0x1c	**TE_SCI_CANNOT_INIT_LOCALSEGMENT**	Cannot initialize local segment
0x1d	**TE_SCI_CANNOT_MAP_REMOTESEGMENT**	Cannot map remote segment
0x1e	**TE_SCI_UNABLE_TO_UNMAP_SEGMENT**	Cannot free the resources used by this segment (step 1)
0x1f	**TE_SCI_UNABLE_TO_REMOVE_SEGMENT**	Cannot free the resources used by this segment (step 2)
0x20	**TE_SCI_UNABLE_TO_DISCONNECT_SEGMENT**	Cannot disconnect from a remote segment
0x21	**TE_SHM_IPC_PERMANENT**	Shm ipc Permanent error
0x22	**TE_SCI_UNABLE_TO_CLOSE_CHANNEL**	Unable to close the sci channel and the resources allocated

22.5.8 NDB Cluster Single User Mode

Single user mode enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of `ndb_restore`. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command in the `ndb_mgm` client to see when the cluster has entered single user mode. You can also check the `status` column of the `ndbinfo.nodes` table (see Section 22.5.10.28, “The ndbinfo nodes Table”, for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is `5` becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node will be rejected.

Note

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:

  1. Finish all single user mode transactions
  2. Issue the `EXIT SINGLE USER MODE` command
  3. Restart the cluster's data nodes

- Method 2:

  Restart storage nodes prior to entering single user mode.

22.5.9 Quick Reference: NDB Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to an NDB Cluster, and in some cases provide information about the cluster itself.

- `SHOW ENGINE NDB STATUS`, `SHOW ENGINE NDBCLUSTER STATUS`

  The output of this statement contains information about the server's connection to the cluster, creation and usage of NDB Cluster objects, and binary logging for NDB Cluster replication.

  See Section 13.7.6.15, “SHOW ENGINE Syntax”, for a usage example and more detailed information.

- `SHOW ENGINES`

This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

See Section 13.7.6.16, “SHOW ENGINES Syntax”, for more detailed information.

Note

This statement does not support a `LIKE` clause. However, you can use `LIKE` to filter queries against the `INFORMATION_SCHEMA.ENGINES` table, as discussed in the next item.

- `SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']`

  This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the `INFORMATION_SCHEMA` database. Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a `LIKE` clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with `NDB` support and, if so, whether it is enabled:

```
mysql> SELECT SUPPORT FROM INFORMATION_SCHEMA.ENGINES
    ->   WHERE ENGINE LIKE 'NDB%';
+---------+
| support |
+---------+
| ENABLED |
+---------+
```

  See Section 25.9, “The INFORMATION_SCHEMA ENGINES Table”, for more information.

- `SHOW VARIABLES LIKE 'NDB%'`

  This statement provides a list of most server system variables relating to the `NDB` storage engine, and their values, as shown here:

```
mysql> SHOW VARIABLES LIKE 'NDB%';
+-----------------------------------+-------+
| Variable_name                     | Value |
+-----------------------------------+-------+
| ndb_autoincrement_prefetch_sz     | 32    |
| ndb_cache_check_time              | 0     |
| ndb_extra_logging                 | 0     |
| ndb_force_send                    | ON    |
| ndb_index_stat_cache_entries      | 32    |
| ndb_index_stat_enable             | OFF   |
| ndb_index_stat_update_freq        | 20    |
| ndb_report_thresh_binlog_epoch_slip | 3     |
| ndb_report_thresh_binlog_mem_usage | 10    |
| ndb_use_copying_alter_table       | OFF   |
| ndb_use_exact_count               | ON    |
| ndb_use_transactions              | ON    |
+-----------------------------------+-------+
```

  See Section 5.1.8, “Server System Variables”, for more information.

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES WHERE VARIABLE_NAME LIKE 'NDB%';`

  This statement is the equivalent of the `SHOW` command described in the previous item, and provides almost identical output, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
    ->   WHERE VARIABLE_NAME LIKE 'NDB%';
+-----------------------------------+----------------+
```

```
| VARIABLE_NAME                       | VARIABLE_VALUE |
+-------------------------------------+----------------+
| NDB_AUTOINCREMENT_PREFETCH_SZ       | 32             |
| NDB_CACHE_CHECK_TIME                | 0              |
| NDB_EXTRA_LOGGING                   | 0              |
| NDB_FORCE_SEND                      | ON             |
| NDB_INDEX_STAT_CACHE_ENTRIES        | 32             |
| NDB_INDEX_STAT_ENABLE               | OFF            |
| NDB_INDEX_STAT_UPDATE_FREQ          | 20             |
| NDB_REPORT_THRESH_BINLOG_EPOCH_SLIP | 3              |
| NDB_REPORT_THRESH_BINLOG_MEM_USAGE  | 10             |
| NDB_USE_COPYING_ALTER_TABLE         | OFF            |
| NDB_USE_EXACT_COUNT                 | ON             |
| NDB_USE_TRANSACTIONS                | ON             |
+-------------------------------------+----------------+
```

Unlike the case with the `SHOW` command, it is possible to select individual columns. For example:

```
mysql> SELECT VARIABLE_VALUE
    ->   FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
    ->   WHERE VARIABLE_NAME = 'ndb_force_send';
+----------------+
| VARIABLE_VALUE |
+----------------+
| ON             |
+----------------+
```

See The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables, and Section 5.1.8, “Server System Variables”, for more information.

- `SHOW STATUS LIKE 'NDB%'`

  This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

  ```
  mysql> SHOW STATUS LIKE 'NDB%';
  +--------------------------+----------------+
  | Variable_name            | Value          |
  +--------------------------+----------------+
  | Ndb_cluster_node_id      | 10             |
  | Ndb_config_from_host     | 198.51.100.103 |
  | Ndb_config_from_port     | 1186           |
  | Ndb_number_of_data_nodes | 4              |
  +--------------------------+----------------+
  ```

  If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in the output of this statement contain a zero or an empty string:

  ```
  mysql> SHOW STATUS LIKE 'NDB%';
  +--------------------------+-------+
  | Variable_name            | Value |
  +--------------------------+-------+
  | Ndb_cluster_node_id      | 0     |
  | Ndb_config_from_host     |       |
  | Ndb_config_from_port     | 0     |
  | Ndb_number_of_data_nodes | 0     |
  +--------------------------+-------+
  ```

  See also Section 13.7.6.35, “SHOW STATUS Syntax”.

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_STATUS WHERE VARIABLE_NAME LIKE 'NDB%';`

This statement provides similar output to the `SHOW` command discussed in the previous item. However, unlike the case with `SHOW STATUS`, it is possible using the `SELECT` to extract values in SQL for use in scripts for monitoring and automation purposes.

See The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables, for more information.

You can also query the tables in the `ndbinfo` information database for real-time data about many NDB Cluster operations. See Section 22.5.10, “ndbinfo: The NDB Cluster Information Database”.

22.5.10 ndbinfo: The NDB Cluster Information Database

`ndbinfo` is a database containing information specific to NDB Cluster.

This database contains a number of tables, each providing a different sort of data about NDB Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

`ndbinfo` is included with NDB Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that `ndbinfo` support is active in a given MySQL Server instance using `SHOW PLUGINS`; if `ndbinfo` support is enabled, you should see a row containing `ndbinfo` in the `Name` column and `ACTIVE` in the `Status` column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
+----------------------------------+--------+--------------------+---------+---------+
| Name                             | Status | Type               | Library | License |
+----------------------------------+--------+--------------------+---------+---------+
| binlog                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| mysql_native_password            | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| sha256_password                  | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| MRG_MYISAM                       | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MEMORY                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| CSV                              | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MyISAM                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| InnoDB                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| INNODB_TRX                       | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_LOCKS                     | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_LOCK_WAITS                | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP                       | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP_RESET                 | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMPMEM                    | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMPMEM_RESET              | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP_PER_INDEX             | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP_PER_INDEX_RESET       | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_BUFFER_PAGE               | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_BUFFER_PAGE_LRU           | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_BUFFER_POOL_STATS         | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_TEMP_TABLE_INFO           | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_METRICS                   | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_FT_DEFAULT_STOPWORD       | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_FT_DELETED                | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_FT_BEING_DELETED          | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_FT_CONFIG                 | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_FT_INDEX_CACHE            | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_FT_INDEX_TABLE            | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_TABLES                | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_TABLESTATS            | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_INDEXES               | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_COLUMNS               | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_FIELDS                | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_FOREIGN               | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_FOREIGN_COLS          | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_TABLESPACES           | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_DATAFILES             | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_SYS_VIRTUAL               | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
```

```
| PERFORMANCE_SCHEMA               | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndbCluster                      | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndbinfo                          | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndb_transid_mysql_connection_map | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| BLACKHOLE                        | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ARCHIVE                          | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| partition                        | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ngram                            | ACTIVE | FTPARSER           | NULL    | GPL     |
+----------------------------------+--------+--------------------+---------+---------+
46 rows in set (0.00 sec)
```

You can also do this by checking the output of `SHOW ENGINES` for a line including `ndbinfo` in the `Engine` column and `YES` in the `Support` column, as shown here (emphasized text):

```
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
      Engine: ndbcluster
     Support: YES
     Comment: Clustered, fault-tolerant tables
Transactions: YES

  Savepoints: NO
10 rows in set (0.00 sec)
```

If `ndbinfo` support is enabled, then you can access `ndbinfo` using SQL statements in `mysql` or another MySQL client. For example, you can see `ndbinfo` listed in the output of `SHOW DATABASES`, as shown here (emphasized text):

```
mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| ndbinfo            |
| performance_schema |
| sys                |
+--------------------+
5 rows in set (0.04 sec)
```

If the `mysqld` process was not started with the `--ndbcluster` option, `ndbinfo` is not available and is not displayed by `SHOW DATABASES`. If `mysqld` was formerly connected to an NDB Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), `ndbinfo` and its tables remain visible, but an attempt to access any tables (other than `blocks` or `config_params`) fails with `Got error 157 'Connection to NDB failed' from NDBINFO`.

With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` “tables” are actually views generated from internal `NDB` tables not normally visible to the MySQL Server.

All `ndbinfo` tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while other are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on `ndbinfo` tables; so joining large `ndbinfo` tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a `WHERE` clause.

`ndbinfo` tables are not included in the query cache. (Bug #59831)

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

```
mysql> USE ndbinfo;
Database changed

mysql> SHOW TABLES;
+---------------------------------+
| Tables_in_ndbinfo               |
+---------------------------------+
| arbitrator_validity_detail      |
| arbitrator_validity_summary     |
| blocks                          |
```

```
| cluster_locks                   |
| cluster_operations              |
| cluster_transactions            |
| config_nodes                    |
| config_params                   |
| config_values                   |
| counters                        |
| cpustat                         |
| cpustat_1sec                    |
| cpustat_20sec                   |
| cpustat_50ms                    |
| dict_obj_info                   |
| dict_obj_types                  |
| disk_write_speed_aggregate      |
| disk_write_speed_aggregate_node |
| disk_write_speed_base           |
| diskpagebuffer                  |
| error_messages                  |
| locks_per_fragment              |
| logbuffers                      |
| logspaces                       |
| membership                      |
| memory_per_fragment             |
| memoryusage                     |
| nodes                           |
| operations_per_fragment         |
| processes                       |
| resources                       |
| restart_info                    |
| server_locks                    |
| server_operations               |
| server_transactions             |
| table_distribution_status       |

| table_replicas                  |
| tc_time_track_stats             |
| threadblocks                    |
| threads                         |
| threadstat                      |
| transporters                    |
+---------------------------------+
44 rows in set (0.00 sec)
```

In NDB 8.0, all `ndbinfo` tables use the `NDB` storage engine; however, an `ndbinfo` entry still appears in the output of `SHOW ENGINES` and `SHOW PLUGINS` as described previously.

You can execute `SELECT` statements against these tables, just as you would normally expect:

```
mysql> SELECT * FROM memoryusage;
+---------+--------------------+--------+------------+------------+-------------+
| node_id | memory_type        | used   | used_pages | total      | total_pages |
+---------+--------------------+--------+------------+------------+-------------+
|       5 | Data memory        | 753664 |         23 | 1073741824 |       32768 |
|       5 | Index memory       | 163840 |         20 | 1074003968 |      131104 |
|       5 | Long message buffer |   2304 |          9 |   67108864 |      262144 |
|       6 | Data memory        | 753664 |         23 | 1073741824 |       32768 |
|       6 | Index memory       | 163840 |         20 | 1074003968 |      131104 |
|       6 | Long message buffer |   2304 |          9 |   67108864 |      262144 |
+---------+--------------------+--------+------------+------------+-------------+
6 rows in set (0.02 sec)
```

More complex queries, such as the two following `SELECT` statements using the `memoryusage` table, are possible:

```
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
     >     FROM memoryusage
     >     WHERE memory_type = 'Data memory';
+-----------------------------+
```

```
| Data Memory Used, All Nodes |
+-----------------------------+
|                        6460 |
+-----------------------------+
1 row in set (0.37 sec)

mysql> SELECT SUM(max) as 'Total IndexMemory Available'
     >     FROM memoryusage
     >     WHERE memory_type = 'Index memory';
+-----------------------------+
| Total IndexMemory Available |
+-----------------------------+
|                       25664 |
+-----------------------------+
1 row in set (0.33 sec)
```

`ndbinfo` table and column names are case sensitive (as is the name of the `ndbinfo` database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

```
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+
| node_id | uptime | status  | start_phase |
+---------+--------+---------+-------------+
|       1 |  13602 | STARTED |           0 |
|       2 |     16 | STARTED |           0 |
+---------+--------+---------+-------------+
2 rows in set (0.04 sec)

mysql> SELECT * FROM Nodes;
ERROR 1146 (42S02): Table 'ndbinfo.Nodes' doesn't exist
```

`mysqldump` ignores the `ndbinfo` database entirely, and excludes it from any output. This is true even when using the `--databases` or `--all-databases` option.

NDB Cluster also maintains tables in the `INFORMATION_SCHEMA` information database, including the `FILES` table which contains information about files used for NDB Cluster Disk Data storage, and the `ndb_transid_mysql_connection_map` table, which shows the relationships between transactions, transaction coordinators, and NDB Cluster API nodes. For more information, see the descriptions of the tables or Section 22.5.11, “INFORMATION_SCHEMA Tables for NDB Cluster”.

22.5.10.1 The ndbinfo arbitrator_validity_detail Table

The `arbitrator_validity_detail` table shows the view that each data node in the cluster has of the arbitrator. It is a subset of the `membership` table.

The following table provides information about the columns in the `arbitrator_validity_detail` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.364 Columns of the arbitrator_validity_detail table

Column Name	Type	Description
`node_id`	integer	This node's node ID
`arbitrator`	integer	Node ID of arbitrator
`arb_ticket`	string	Internal identifier used to track arbitration
`arb_connected`	`Yes` or `No`	Whether this node is connected to the arbitrator
`arb_state`	Enumeration (see text)	Arbitration state

The node ID is the same as that reported by `ndb_mgm -e "SHOW"`.

All nodes should show the same `arbitrator` and `arb_ticket` values as well as the same `arb_state` value. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether the current node is connected to the `arbitrator`.

22.5.10.2 The ndbinfo arbitrator_validity_summary Table

The `arbitrator_validity_summary` table provides a composite view of the arbitrator with regard to the cluster's data nodes.

The following table provides information about the columns in the `arbitrator_validity_summary` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.365 Columns of the arbitrator_validity_summary table

Column Name	Type	Description
`arbitrator`	integer	Node ID of arbitrator
`arb_ticket`	string	Internal identifier used to track arbitration
`arb_connected`	`Yes` or `No`	Whether this arbitrator is connected to the cluster
`consensus_count`	integer	Number of data nodes that see this node as arbitrator

In normal operations, this table should have only 1 row for any appreciable length of time. If it has more than 1 row for longer than a few moments, then either not all nodes are connected to the arbitrator, or all nodes are connected, but do not agree on the same arbitrator.

The `arbitrator` column shows the arbitrator's node ID.

`arb_ticket` is the internal identifier used by this arbitrator.

`arb_connected` shows whether this node is connected to the cluster as an arbitrator.

22.5.10.3 The ndbinfo blocks Table

The `blocks` table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see NDB Kernel Blocks). It is for use by the other `ndbinfo` tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The following table provides information about the columns in the `blocks` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.366 Columns of the blocks table

Column Name	Type	Description
`block_number`	integer	Block number
`block_name`	string	Block name

To obtain a list of all block names, simply execute `SELECT block_name FROM ndbinfo.blocks`. Although this is a static table, its content can vary between different NDB Cluster releases.

22.5.10.4 The ndbinfo cluster_locks Table

The `cluster_locks` table provides information about current lock requests holding and waiting for locks on `NDB` tables in an NDB Cluster, and is intended as a companion table to

cluster_operations. Information obtain from the cluster_locks table may be useful in investigating stalls and deadlocks.

The following table provides information about the columns in the cluster_locks table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.367 Columns of the cluster_locks table

Column Name	Type	Description
node_id	integer	ID of reporting node
block_instance	integer	ID of reporting LDM instance
tableid	integer	ID of table containing this row
fragmentid	integer	ID of fragment containing locked row
rowid	integer	ID of locked row
transid	integer	Transaction ID
mode	string	Lock request mode
state	string	Lock state
detail	string	Whether this is first holding lock in row lock queue
op	string	Operation type
duration_millis	integer	Milliseconds spent waiting or holding lock
lock_num	integer	ID of lock object
waiting_for	integer	Waiting for lock with this ID

The table ID (tableid column) is assigned internally, and is the same as that used in other ndbinfo tables. It is also shown in the output of ndb_show_tables.

The transaction ID (transid column) is the identifier generated by the NDB API for the transaction requesting or holding the current lock.

The mode column shows the lock mode; this is always one of S (indicating a shared lock) or X (an exclusive lock). If a transaction holds an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The state column shows the lock state. Its value is always one of H (holding) or W (waiting). A waiting lock request waits for a lock held by a different transaction.

When the detail column contains a * (asterisk character), this means that this lock is the first holding lock in the affected row's lock queue; otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The op column shows the type of operation requesting the lock. This is always one of the values READ, INSERT, UPDATE, DELETE, SCAN, or REFRESH.

The duration_millis column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (lockid column) is unique to this node and block instance.

The lock state is shown in the lock_state column; if this is W, the lock is waiting to be granted, and the waiting_for column shows the lock ID of the lock object this request is waiting for. Otherwise, the waiting_for column is empty. waiting_for can refer only to locks on the same row, as identified by node_id, block_instance, tableid, fragmentid, and rowid.

22.5.10.5 The ndbinfo cluster_operations Table

The `cluster_operations` table provides a per-operation (stateful primary key op) view of all activity in the NDB Cluster from the point of view of the local data management (LQH) blocks (see The DBLQH Block).

The following table provides information about the columns in the `cluster_operations` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.368 Columns of the cluster_operations table

Column Name	Type	Description
`node_id`	integer	Node ID of reporting LQH block
`block_instance`	integer	LQH block instance
`transid`	integer	Transaction ID
`operation_type`	string	Operation type (see text for possible values)
`state`	string	Operation state (see text for possible values)
`tableid`	integer	Table ID
`fragmentid`	integer	Fragment ID
`client_node_id`	integer	Client node ID
`client_block_ref`	integer	Client block reference
`tc_node_id`	integer	Transaction coordinator node ID
`tc_block_no`	integer	Transaction coordinator block number
`tc_block_instance`	integer	Transaction coordinator block instance

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dblqh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an `NDB` table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` and `tc_block_instance` column provide, respectively, the `DBLQH` and `DBTC` block instance numbers. You can use these along with the block names to obtain information about specific threads from the `threadblocks` table.

22.5.10.6 The ndbinfo cluster_transactions Table

The `cluster_transactions` table shows information about all ongoing transactions in an NDB Cluster.

The following table provides information about the columns in the `cluster_transactions` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.369 Columns of the cluster_transactions table

Column Name	Type	Description
`node_id`	integer	Node ID of transaction coordinator
`block_instance`	integer	TC block instance
`transid`	integer	Transaction ID
`state`	string	Operation state (see text for possible values)
`count_operations`	integer	Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations)
`outstanding_operations`	integer	Operations still being executed in local data management blocks
`inactive_seconds`	integer	Time spent waiting for API
`client_node_id`	integer	Client node ID
`client_block_ref`	integer	Client block reference

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The `state` column can have any one of the values `CS_ABORTING`, `CS_COMMITTING`, `CS_COMMIT_SENT`, `CS_COMPLETE_SENT`, `CS_COMPLETING`, `CS_CONNECTED`, `CS_DISCONNECTED`, `CS_FAIL_ABORTED`, `CS_FAIL_ABORTING`, `CS_FAIL_COMMITTED`, `CS_FAIL_COMMITTING`, `CS_FAIL_COMPLETED`, `CS_FAIL_PREPARED`, `CS_PREPARE_TO_COMMIT`, `CS_RECEIVING`, `CS_REC_COMMITTING`, `CS_RESTART`, `CS_SEND_FIRE_TRIG_REQ`, `CS_STARTED`, `CS_START_COMMITTING`, `CS_START_SCAN`, `CS_WAIT_ABORT_CONF`, `CS_WAIT_COMMIT_CONF`, `CS_WAIT_COMPLETE_CONF`, `CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dbtc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `tc_block_instance` column provides the `DBTC` block instance number. You can use this along with the block name to obtain information about specific threads from the `threadblocks` table.

22.5.10.7 The ndbinfo config_nodes Table

The `config_nodes` table shows nodes configured in an NDB Cluster `config.ini` file. For each node, the table displays a row containing the node ID, the type of node (management node, data node, or API node), and the name or IP address of the host on which the node is configured to run.

This table does not indicate whether a given node is actually running, or whether it is currently connected to the cluster. Information about nodes connected to an NDB Cluster can be obtained from the `nodes` and `processes` table.

The following table provides information about the columns in the `config_nodes` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.370 Columns of the config_params table

Column Name	Type	Description
`node_id`	integer	The node's ID
`node_type`	string	The type of node
`node_hostname`	string	The name or IP address of the host on which the node resides

The `node_id` column shows the node ID used in the `config.ini` file for this node; if none is specified, the node ID that would be assigned automatically to this node is displayed.

The `node_type` column displays one of the following three values:

- `MGM`: Management node.
- `NDB`: Data node.
- `API`: API node; this includes SQL nodes.

The `node_hostname` column shows the node host as specified in the `config.ini` file. This can be empty for an API node, if `HostName` has not been set in the cluster configuration file. If `HostName` has not been set for a data node in the configuration file, `localhost` is used here. `localhost` is also used if `HostName` has not been specified for a management node.

22.5.10.8 The ndbinfo config_params Table

The `config_params` table is a static table which provides the names and internal ID numbers of and other information about NDB Cluster configuration parameters.

The following table provides information about the columns in the `config_params` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table. This table can also be used in conjunction with the `config_values` table for obtaining realtime information about node configuration parameters.

Table 22.371 Columns of the config_params table

Column Name	Type	Description
`param_number`	integer	The parameter's internal ID number
`param_name`	string	The name of the parameter
`param_description`	string	A brief description of the parameter
`param_type`	string	The parameter's data type
`param_default`	string	The parameter's default value, if any
`param_min`	string	The parameter's maximum value, if any
`param_max`	string	The parameter's minimum value, if any
`param_mandatory`	integer	This is 1 if the parameter is required, otherwise 0
`param_status`	string	Currently unused

This table is read-only.

Although this is a static table, its content can vary between NDB Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

22.5.10.9 The ndbinfo config_values Table

The `config_values` table provides information about the current state of node configuration parameter values. Each row in the table corresponds to the current value of a parameter on a given node.

Table 22.372 Columns of the config_params table

Column Name	Type	Description
`node_id`	integer	ID of the node in the cluster
`config_param`	integer	The parameter's internal ID number
`config_value`	string	Current value of the parameter

This table's `config_param` column and the `config_params` table's `param_number` column use the same parameter identifiers. By joining the two tables on these columns, you can obtain detailed information about desired node configuration parameters. The query shown here provides the current values for all parameters on each data node in the cluster, ordered by node ID and parameter name:

```
SELECT    v.node_id AS 'Node Id',
          p.param_name AS 'Parameter',
          v.config_value AS 'Value'
FROM      config_values v
JOIN      config_params p
ON        v.config_param=p.param_number
WHERE     p.param_name NOT LIKE '\_\_%'
ORDER BY  v.node_id, p.param_name;
```

Partial output from the previous query when run on a small example cluster used for simple testing:

```
+---------+----------------------------------------+----------------+
| Node Id | Parameter                              | Value          |
+---------+----------------------------------------+----------------+
|       2 | Arbitration                            | 1              |
|       2 | ArbitrationTimeout                     | 7500           |
|       2 | BackupDataBufferSize                   | 16777216       |
|       2 | BackupDataDir                          | /home/jon/data |
|       2 | BackupDiskWriteSpeedPct                | 50             |
|       2 | BackupLogBufferSize                    | 16777216       |

...

|       3 | TotalSendBufferMemory                  | 0              |
|       3 | TransactionBufferMemory                | 1048576        |
|       3 | TransactionDeadlockDetectionTimeout    | 1200           |
|       3 | TransactionInactiveTimeout             | 4294967039     |
|       3 | TwoPassInitialNodeRestartCopy          | 0              |
|       3 | UndoDataBuffer                         | 16777216       |
|       3 | UndoIndexBuffer                        | 2097152        |
+---------+----------------------------------------+----------------+
248 rows in set (0.02 sec)
```

The `WHERE` clause filters out parameters whose names begin with a double underscore (`__`); these parameters are reserved for testing and other internal uses by the NDB developers, and are not intended for use in a production NDB Cluster.

You can obtain output that is more specific, more detailed, or both by issuing the proper queries. This example provides all types of available information about the `NodeId`, `NoOfReplicas`, `HostName`, `DataMemory`, `IndexMemory`, and `TotalSendBufferMemory` parameters as currently set for all data nodes in the cluster:

```
SELECT  p.param_name AS Name,
        v.node_id AS Node,
        p.param_type AS Type,
```

```
        p.param_default AS 'Default',
        p.param_min AS Minimum,
        p.param_max AS Maximum,
        CASE p.param_mandatory WHEN 1 THEN 'Y' ELSE 'N' END AS 'Required',
        v.config_value AS Current
FROM    config_params p
JOIN    config_values v
ON      p.param_number = v.config_param
WHERE   p. param_name
  IN ('NodeId', 'NoOfReplicas', 'HostName',
      'DataMemory', 'IndexMemory', 'TotalSendBufferMemory')\G
```

The output from this query when run on a small NDB Cluster with 2 data nodes used for simple testing is shown here:

```

22.5.10.10 The ndbinfo counters Table

The `counters` table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The following table provides information about the columns in the `counters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.373 Columns of the counters table

Column Name	Type	Description
`node_id`	integer	The data node ID
`block_name`	string	Name of the associated NDB kernel block (see NDB Kernel Blocks).
`block_instance`	integer	Block instance
`counter_id`	integer	The counter's internal ID number; normally an integer between 1 and 10, inclusive.
`counter_name`	string	The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated.
`val`	integer	The counter's value

Each counter is associated with a particular NDB kernel block.

The `OPERATIONS` counter is associated with the `DBLQH` (local query handler) kernel block (see The DBLQH Block). A primary-key read counts as one operation, as does a primary-key update. For reads,

there is one operation in DBLQH per operation in DBTC. For writes, there is one operation counted per replica.

The ATTRINFO, TRANSACTIONS, COMMITS, READS, LOCAL_READS, SIMPLE_READS, WRITES, LOCAL_WRITES, ABORTS, TABLE_SCANS, and RANGE_SCANS counters are associated with the DBTC (transaction co-ordinator) kernel block (see The DBTC Block).

LOCAL_WRITES and LOCAL_READS are primary-key operations using a transaction coordinator in a node that also holds the primary replica of the record.

The READS counter includes all reads. LOCAL_READS includes only those reads of the primary replica on the same node as this transaction coordinator. SIMPLE_READS includes only those reads in which the read operation is the beginning and ending operation for a given transaction. Simple reads do not hold locks but are part of a transaction, in that they observe uncommitted changes made by the transaction containing them but not of any other uncommitted transactions. Such reads are “simple” from the point of view of the TC block; since they hold no locks they are not durable, and once DBTC has routed them to the relevant LQH block, it holds no state for them.

ATTRINFO keeps a count of the number of times an interpreted program is sent to the data node. See NDB Protocol Messages, for more information about ATTRINFO messages in the NDB kernel.

The LOCAL_TABLE_SCANS_SENT, READS_RECEIVED, PRUNED_RANGE_SCANS_RECEIVED, RANGE_SCANS_RECEIVED, LOCAL_READS_SENT, CONST_PRUNED_RANGE_SCANS_RECEIVED, LOCAL_RANGE_SCANS_SENT, REMOTE_READS_SENT, REMOTE_RANGE_SCANS_SENT, READS_NOT_FOUND, SCAN_BATCHES_RETURNED, TABLE_SCANS_RECEIVED, and SCAN_ROWS_RETURNED counters are associated with the DBSPJ (select push-down join) kernel block (see The DBSPJ Block).

The block_name and block_instance columns provide, respectively, the applicable NDB kernel block name and instance number. You can use these to obtain information about specific threads from the threadblocks table.

A number of counters provide information about transporter overload and send buffer sizing when troubleshooting such issues. For each LQH instance, there is one instance of each counter in the following list:

- LQHKEY_OVERLOAD: Number of primary key requests rejected at the LQH block instance due to transporter overload
- LQHKEY_OVERLOAD_TC: Count of instances of LQHKEY_OVERLOAD where the TC node transporter was overloaded
- LQHKEY_OVERLOAD_READER: Count of instances of LQHKEY_OVERLOAD where the API reader (reads only) node was overloaded.
- LQHKEY_OVERLOAD_NODE_PEER: Count of instances of LQHKEY_OVERLOAD where the next backup data node (writes only) was overloaded
- LQHKEY_OVERLOAD_SUBSCRIBER: Count of instances of LQHKEY_OVERLOAD where a event subscriber (writes only) was overloaded.
- LQHSCAN_SLOWDOWNS: Count of instances where a fragment scan batch size was reduced due to scanning API transporter overload.

22.5.10.11 The ndbinfo cpustat Table

The cpustat table provides per-thread CPU statistics gathered each second, for each thread running in the NDB kernel.

The following table provides information about the columns in the cpustat table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.374 Columns of the cpustat table

Column Name	Type	Description
node_id	integer	ID of the node where the thread is running
thr_no	integer	Thread ID (specific to this node)
OS_user	integer	OS user time
OS_system	integer	OS system time
OS_idle	integer	OS idle time
thread_exec	integer	Thread execution time
thread_sleeping	integer	Thread sleep time
thread_send	integer	Thread send time
thread_buffer_full	integer	Thread buffer full time
elapsed_time	integer	Elapsed time

22.5.10.12 The ndbinfo cpustat_50ms Table

The cpustat_50ms table provides raw, per-thread CPU data obtained each 50 milliseconds for each thread running in the NDB kernel.

Like cpustat_1sec and cpustat_20sec, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, cpsustat_50ms provides 1 second of history.

The following table provides information about the columns in the cpustat_50ms table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.375 Columns of the cpustat_50ms table

Column Name	Type	Description
node_id	integer	ID of the node where the thread is running
thr_no	integer	Thread ID (specific to this node)
OS_user_time	integer	OS user time
OS_system_time	integer	OS system time
OS_idle_time	integer	OS idle time
exec_time	integer	Thread execution time
sleep_time	integer	Thread sleep time
send_time	integer	Thread send time
buffer_full_time	integer	Thread buffer full time
elapsed_time	integer	Elapsed time

22.5.10.13 The ndbinfo cpustat_1sec Table

The cpustat-1sec table provides raw, per-thread CPU data obtained each second for each thread running in the NDB kernel.

Like cpustat_50ms and cpustat_20sec, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, cpsustat_1sec provides 20 seconds of history.

The following table provides information about the columns in the cpustat_1sec table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.376 Columns of the cpustat_1sec table

Column Name	Type	Description
node_id	integer	ID of the node where the thread is running
thr_no	integer	Thread ID (specific to this node)
OS_user_time	integer	OS user time
OS_system_time	integer	OS system time
OS_idle_time	integer	OS idle time
exec_time	integer	Thread execution time
sleep_time	integer	Thread sleep time
send_time	integer	Thread send time
buffer_full_time	integer	Thread buffer full time
elapsed_time	integer	Elapsed time

22.5.10.14 The ndbinfo cpustat_20sec Table

The cpustat_20sec table provides raw, per-thread CPU data obtained each 20 seconds, for each thread running in the NDB kernel.

Like cpustat_50ms and cpustat_1sec, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, cpsustat_20sec provides 400 seconds of history.

The following table provides information about the columns in the cpustat_20sec table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.377 Columns of the cpustat_20sec table

Column Name	Type	Description
node_id	integer	ID of the node where the thread is running
thr_no	integer	Thread ID (specific to this node)
OS_user_time	integer	OS user time
OS_system_time	integer	OS system time
OS_idle_time	integer	OS idle time
exec_time	integer	Thread execution time
sleep_time	integer	Thread sleep time
send_time	integer	Thread send time
buffer_full_time	integer	Thread buffer full time
elapsed_time	integer	Elapsed time

22.5.10.15 The ndbinfo dict_obj_info Table

The dict_obj_info table provides information about NDB data dictionary (DICT) objects such as tables and indexes. (The dict_obj_types table can be queried for a list of all the types.) This information includes the object's type, state, parent object (if any), and fully qualified name.

The following table provides information about the columns in the dict_obj_info table. For each column, the table shows the name, data type, and a brief description.

Table 22.378 Columns of the dict_obj_info table

Column Name	Type	Description
type	integer	Type of DICT object; join on dict_obj_types to obtain the name

Column Name	Type	Description
id	integer	Object identifier
version	integer	Object version
state	integer	Object state
parent_obj_type	integer	Parent object's type (a dict_obj_types type ID); 0 indicates that the object has no parent
parent_obj_id	integer	Parent object ID (such as a base table); 0 indicates that the object has no parent
fq_name	string	Fully qualified object name; for a table, this has the form *database_name*/def/*table_name*, for a primary key, the form is sys/def/*table_id*/PRIMARY, and for a unique key it is sys/def/*table_id*/*uk_name*$unique

22.5.10.16 The ndbinfo dict_obj_types Table

The dict_obj_types table is a static table listing possible dictionary object types used in the NDB kernel. These are the same types defined by Object::Type in the NDB API.

The following table provides information about the columns in the dict_obj_types table. For each column, the table shows the name, data type, and a brief description.

Table 22.379 Columns of the dict_obj_types table

Column Name	Type	Description
type_id	integer	The type ID for this type
type_name	string	The name of this type

22.5.10.17 The ndbinfo disk_write_speed_base Table

The disk_write_speed_base table provides base information about the speed of disk writes during LCP, backup, and restore operations.

The following table provides information about the columns in the disk_write_speed_base table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.380 Columns of the disk_write_speed_base table

Column Name	Type	Description
node_id	integer	Node ID of this node
thr_no	integer	Thread ID of this LDM thread
millis_ago	integer	Milliseconds since this reporting period ended
millis_passed	integer	Milliseconds elapsed in this reporting period
backup_lcp_bytes_written	integer	Number of bytes written to disk by local checkpoints and backup processes during this period
redo_bytes_written	integer	Number of bytes written to REDO log during this period
target_disk_write_speed	integer	Actual speed of disk writes per LDM thread (base data)

22.5.10.18 The ndbinfo disk_write_speed_aggregate Table

The `disk_write_speed_aggregate` table provides aggregated information about the speed of disk writes during LCP, backup, and restore operations.

The following table provides information about the columns in the `disk_write_speed_aggregate` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.381 Columns in the disk_write_speed_aggregate table

Column Name	Type	Description
node_id	integer	Node ID of this node
thr_no	integer	Thread ID of this LDM thread
backup_lcp_speed_last_sec	integer	Number of bytes written to disk by backup and LCP processes in the last second
redo_speed_last_sec	integer	Number of bytes written to REDO log in the last second
backup_lcp_speed_last_10sec	integer	Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds
redo_speed_last_10sec	integer	Number of bytes written to REDO log per second, averaged over the last 10 seconds
std_dev_backup_lcp_speed_last_10sec	integer	Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds
std_dev_redo_speed_last_10sec	integer	Standard deviation in number of bytes written to REDO log per second, averaged over the last 10 seconds
backup_lcp_speed_last_60sec	integer	Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds
redo_speed_last_60sec	integer	Number of bytes written to REDO log per second, averaged over the last 10 seconds
std_dev_backup_lcp_speed_last_60sec	integer	Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds
std_dev_redo_speed_last_60sec	integer	Standard deviation in number of bytes written to REDO log per second, averaged over the last 60 seconds
slowdowns_due_to_io_lag	integer	Number of seconds since last node start that disk writes were slowed due to REDO log I/O lag
slowdowns_due_to_high_cpu	integer	Number of seconds since last node start that disk writes were slowed due to high CPU usage
disk_write_speed_set_to_min	integer	Number of seconds since last node start that disk write speed was set to minimum
current_target_disk_write_speed	integer	Actual speed of disk writes per LDM thread (aggregated)

22.5.10.19 The ndbinfo disk_write_speed_aggregate_node Table

The `disk_write_speed_aggregate_node` table provides aggregated information per node about the speed of disk writes during LCP, backup, and restore operations.

The following table provides information about the columns in the `disk_write_speed_aggregate_node` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.382 Columns of the disk_write_speed_aggregate_node table

Column Name	Type	Description
node_id	integer	Node ID of this node
backup_lcp_speed_last_sec	integer	Number of bytes written to disk by backup and LCP processes in the last second
redo_speed_last_sec	integer	Number of bytes written to REDO log in the last second
backup_lcp_speed_last_10sec	integer	Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds
redo_speed_last_10sec	integer	Number of bytes written to REDO log per second, averaged over the last 10 seconds
backup_lcp_speed_last_60sec	integer	Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds
redo_speed_last_60sec	integer	Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

22.5.10.20 The ndbinfo diskpagebuffer Table

The `diskpagebuffer` table provides statistics about disk page buffer usage by NDB Cluster Disk Data tables.

The following table provides information about the columns in the `diskpagebuffer` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.383 Columns of the diskpagebuffer table

Column Name	Type	Description
`node_id`	integer	The data node ID
`block_instance`	integer	Block instance
`pages_written`	integer	Number of pages written to disk.
`pages_written_lcp`	integer	Number of pages written by local checkpoints.
`pages_read`	integer	Number of pages read from disk
`log_waits`	integer	Number of page writes waiting for log to be written to disk
`page_requests_direct_return`	integer	Number of requests for pages that were available in buffer
`page_requests_wait_queue`	integer	Number of requests that had to wait for pages to become available in buffer
`page_requests_wait_io`	integer	Number of requests that had to be read from pages on disk (pages were unavailable in buffer)

You can use this table with NDB Cluster Disk Data tables to determine whether `DiskPageBufferMemory` is sufficiently large to allow data to be read from the buffer rather from disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from `DiskPageBufferMemory` to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```
SELECT
  node_id,
  100 * page_requests_direct_return /
    (page_requests_direct_return + page_requests_wait_io)
      AS hit_ratio
FROM ndbinfo.diskpagebuffer;
```

The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):

```
+---------+-----------+
| node_id | hit_ratio |
+---------+-----------+
|       5 |   97.6744 |
|       6 |   97.6879 |
|       7 |   98.1776 |
|       8 |   98.1343 |
+---------+-----------+
4 rows in set (0.00 sec)
```

`hit_ratio` values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for `DiskPageBufferMemory` needs to be increased in the `config.ini` file.

Note

A change in `DiskPageBufferMemory` requires a rolling restart of all of the cluster's data nodes before it takes effect.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table. Using this information, you can obtain information about disk page buffer metrics relating to individual threads; an example query using `LIMIT 1` to limit the output to a single thread is shown here:

```
mysql> SELECT
     >   node_id, thr_no, block_name, thread_name, pages_written,
     >   pages_written_lcp, pages_read, log_waits,
     >   page_requests_direct_return, page_requests_wait_queue,
     >   page_requests_wait_io
     > FROM ndbinfo.diskpagebuffer
     >   INNER JOIN ndbinfo.threadblocks USING (node_id, block_instance)
     >   INNER JOIN ndbinfo.threads USING (node_id, thr_no)
     > WHERE block_name = 'PGMAN' LIMIT 1\G
*************************** 1. row ***************************
                   node_id: 1
                    thr_no: 1
                block_name: PGMAN
               thread_name: rep
             pages_written: 0
          pages_written_lcp: 0
                pages_read: 1
                 log_waits: 0
page_requests_direct_return: 4
   page_requests_wait_queue: 0
      page_requests_wait_io: 1
1 row in set (0.01 sec)
```

22.5.10.21 The ndbinfo error_messages Table

The `error_messages` table provides information about

The following table provides information about the columns in the `error_messages` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.384 Columns of the error_messages table

Column Name	Type	Description
`error_code`	integer	Numeric error code
`error_description`	string	Description of error
`error_status`	string	Error status code
`error_classification`	integer	Error classification code

`error_code` is a numeric NDB error code. This is the same error code that can be supplied to `ndb_perror` or `perror --ndb`.

`error_description` provides a basic description of the condition causing the error.

The `error_status` column provides status information relating to the error. Possible values for this column are listed here:

- `No error`
- `Illegal connect string`
- `Illegal server handle`
- `Illegal reply from server`
- `Illegal number of nodes`
- `Illegal node status`
- `Out of memory`
- `Management server not connected`
- `Could not connect to socket`
- `Start failed`
- `Stop failed`
- `Restart failed`
- `Could not start backup`
- `Could not abort backup`
- `Could not enter single user mode`
- `Could not exit single user mode`
- `Failed to complete configuration change`
- `Failed to get configuration`
- `Usage error`
- `Success`

- `Permanent error`
- `Temporary error`
- `Unknown result`
- `Temporary error, restart node`
- `Permanent error, external action needed`
- `Ndbd file system error, restart node initial`
- `Unknown`

The error_classification column shows the error classification. See NDB Error Classifications, for information about classification codes and their meanings.

22.5.10.22 The ndbinfo locks_per_fragment Table

The `locks_per_fragment` table provides information about counts of lock claim requests, and the outcomes of these requests on a per-fragment basis, serving as a companion table to `operations_per_fragment` and `memory_per_fragment`. This table also shows the total time spent waiting for locks successfully and unsuccessfully since fragment or table creation, or since the most recent restart.

The following table provides information about the columns in the `locks_per_fragment` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.385 Columns of the locks_per_fragment table

Column Name	Type	Description
`fq_name`	string	Fully qualified table name
`parent_fq_name`	string	Fully qualified name of parent object
`type`	string	Table type; see text for possible values
`table_id`	integer	Table ID
`node_id`	integer	Reporting node ID
`block_instance`	integer	LDM instance ID
`fragment_num`	integer	Fragment identifier
`ex_req`	integer	Exclusive lock requests started
`ex_imm_ok`	integer	Exclusive lock requests immediately granted
`ex_wait_ok`	integer	Exclusive lock requests granted following wait
`ex_wait_fail`	integer	Exclusive lock requests not granted
`sh_req`	integer	Shared lock requests started
`sh_imm_ok`	integer	Shared lock requests immediately granted
`sh_wait_ok`	integer	Shared lock requests granted following wait
`sh_wait_fail`	integer	Shared lock requests not granted
`wait_ok_millis`	integer	Time spent waiting for lock requests that were granted, in milliseconds
`wait_fail_millis`	integer	Time spent waiting for lock requests that failed, in milliseconds

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

`fq_name` is a fully qualified database object name in *`database`*/*`schema`*/*`name`* format, such as `test/def/t1` or `sys/def/10/b$unique`.

`parent_fq_name` is the fully qualified name of this object's parent object (table).

`table_id` is the table's internal ID generated by `NDB`. This is the same internal table ID shown in other `ndbinfo` tables; it is also visible in the output of `ndb_show_tables`.

The `type` column shows the type of table. This is always one of `System table`, `User table`, `Unique hash index`, `Hash index`, `Unique ordered index`, `Ordered index`, `Hash index trigger`, `Subscription trigger`, `Read only constraint`, `Index trigger`, `Reorganize trigger`, `Tablespace`, `Log file group`, `Data file`, `Undo file`, `Hash map`, `Foreign key definition`, `Foreign key parent trigger`, `Foreign key child trigger`, or `Schema transaction`.

The values shown in all of the columns `ex_req`, `ex_req_imm_ok`, `ex_wait_ok`, `ex_wait_fail`, `sh_req`, `sh_req_imm_ok`, `sh_wait_ok`, and `sh_wait_fail` represent cumulative numbers of requests since the table or fragment was created, or since the last restart of this node, whichever of these occurred later. This is also true for the time values shown in the `wait_ok_millis` and `wait_fail_millis` columns.

Every lock request is considered either to be in progress, or to have completed in some way (that is, to have succeeded or failed). This means that the following relationships are true:

```
ex_req >= (ex_req_imm_ok + ex_wait_ok + ex_wait_fail)

sh_req >= (sh_req_imm_ok + sh_wait_ok + sh_wait_fail)
```

The number of requests currently in progress is the current number of incomplete requests, which can be found as shown here:

```
[exclusive lock requests in progress] =
    ex_req - (ex_req_imm_ok + ex_wait_ok + ex_wait_fail)

[shared lock requests in progress] =
    sh_req - (sh_req_imm_ok + sh_wait_ok + sh_wait_fail)
```

A failed wait indicates an aborted transaction, but the abort may or may not be caused by a lock wait timeout. You can obtain the total number of aborts while waiting for locks as shown here:

```
[aborts while waiting for locks] = ex_wait_fail + sh_wait_fail
```

22.5.10.23 The ndbinfo logbuffers Table

The `logbuffer` table provides information on NDB Cluster log buffer usage.

The following table provides information about the columns in the `logbuffers` table. For each column, the table shows the name, data type, and a brief description.

Table 22.386 Columns in the logbuffers table

Column Name	Type	Description
`node_id`	integer	The ID of this data node.
`log_type`	string	Type of log. One of: `REDO`, `DD-UNDO`, `BACKUP-DATA`, or `BACKUP-LOG`.
`log_id`	integer	The log ID.
`log_part`	integer	The log part number.
`total`	integer	Total space available for this log.
`used`	integer	Space used by this log.

`logbuffers` table rows reflecting two additional log types are available when performing an NDB backup. One of these rows has the log type `BACKUP-DATA`, which shows the amount of data buffer used during backup to copy fragments to backup files. The other row has the log type `BACKUP-LOG`, which displays the amount of log buffer used during the backup to record changes made after the backup has started. One each of these `log_type` rows is shown in the `logbuffers` table for each data node in the cluster. These rows are not present unless an NDB backup is currently being performed.

22.5.10.24 The ndbinfo logspaces Table

This table provides information about NDB Cluster log space usage.

The following table provides information about the columns in the `logspaces` table. For each column, the table shows the name, data type, and a brief description.

Table 22.387 Columns in the logspaces table

Column Name	Type	Description
`node_id`	integer	The ID of this data node.
`log_type`	string	Type of log; one of: `REDO` or `DD-UNDO`.
`log_id`	integer	The log ID.
`log_part`	integer	The log part number.
`total`	integer	Total space available for this log.
`used`	integer	Space used by this log.

22.5.10.25 The ndbinfo membership Table

The `membership` table describes the view that each data node has of all the others in the cluster, including node group membership, president node, arbitrator, arbitrator successor, arbitrator connection states, and other information.

The following table provides information about the columns in the `membership` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.388 Columns of the membership table

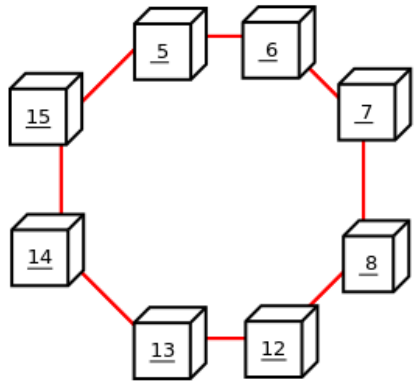
Column Name	Type	Description
`node_id`	integer	This node's node ID
`group_id`	integer	Node group to which this node belongs
`left node`	integer	Node ID of the previous node
`right_node`	integer	Node ID of the next node
`president`	integer	President's node ID
`successor`	integer	Node ID of successor to president
`succession_order`	integer	Order in which this node succeeds to presidency
`Conf_HB_order`	integer	-
`arbitrator`	integer	Node ID of arbitrator
`arb_ticket`	string	Internal identifier used to track arbitration
`arb_state`	Enumeration (see text)	Arbitration state
`arb_connected`	`Yes` or `No`	Whether this node is connected to the arbitrator
`connected_rank1_arbs`	List of node IDs	Connected arbitrators of rank 1

Column Name	Type	Description
connected_rank2_arbs	List of node IDs	Connected arbitrators of rank 1

The node ID and node group ID are the same as reported by `ndb_mgm -e "SHOW"`.

`left_node` and `right_node` are defined in terms of a model that connects all data nodes in a circle, in order of their node IDs, similar to the ordering of the numbers on a clock dial, as shown here:

Figure 22.26 Circular Arrangement of NDB Cluster Nodes



In this example, we have 8 data nodes, numbered 5, 6, 7, 8, 12, 13, 14, and 15, ordered clockwise in a circle. We determine “left” and “right” from the interior of the circle. The node to the left of node 5 is node 15, and the node to the right of node 5 is node 6. You can see all these relationships by running the following query and observing the output:

```
mysql> SELECT node_id,left_node,right_node
    -> FROM ndbinfo.membership;
+---------+-----------+------------+
| node_id | left_node | right_node |
+---------+-----------+------------+
|       5 |        15 |          6 |
|       6 |         5 |          7 |
|       7 |         6 |          8 |
|       8 |         7 |         12 |
|      12 |         8 |         13 |
|      13 |        12 |         14 |
|      14 |        13 |         15 |
|      15 |        14 |          5 |
+---------+-----------+------------+
8 rows in set (0.00 sec)
```

The designations “left” and “right” are used in the event log in the same way.

The `president` node is the node viewed by the current node as responsible for setting an arbitrator (see NDB Cluster Start Phases). If the president fails or becomes disconnected, the current node expects the node whose ID is shown in the `successor` column to become the new president. The `succession_order` column shows the place in the succession queue that the current node views itself as having.

In a normal NDB Cluster, all data nodes should see the same node as `president`, and the same node (other than the president) as its `successor`. In addition, the current president should see itself as `1` in the order of succession, the `successor` node should see itself as `2`, and so on.

All nodes should show the same `arb_ticket` values as well as the same `arb_state` values. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether this node is connected to the node shown as this node's `arbitrator`.

The `connected_rank1_arbs` and `connected_rank2_arbs` columns each display a list of 0 or more arbitrators having an `ArbitrationRank` equal to 1, or to 2, respectively.

Note

Both management nodes and API nodes are eligible to become arbitrators.

22.5.10.26 The ndbinfo memoryusage Table

Querying this table provides information similar to that provided by the `ALL REPORT MemoryUsage` command in the `ndb_mgm` client, or logged by `ALL DUMP 1000`.

The following table provides information about the columns in the `memoryusage` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.389 Columns of the memoryusage table

Column Name	Type	Description
`node_id`	integer	The node ID of this data node.
`memory_type`	string	One of `Data memory`, `Index memory`, or `Long message buffer`.
`used`	integer	Number of bytes currently used for data memory or index memory by this data node.
`used_pages`	integer	Number of pages currently used for data memory or index memory by this data node; see text.
`total`	integer	Total number of bytes of data memory or index memory available for this data node; see text.
`total_pages`	integer	Total number of memory pages available for data memory or index memory on this data node; see text.

The `total` column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the `config.ini` file.

Suppose that the cluster has 2 data nodes having node IDs `5` and `6`, and the `config.ini` file contains the following:

```
[ndbd default]
DataMemory = 1G
IndexMemory = 1G
```

Suppose also that the value of the `LongMessageBuffer` configuration parameter is allowed to assume its default (64 MB).

The following query shows approximately the same values:

```
mysql> SELECT node_id, memory_type, total
     > FROM ndbinfo.memoryusage;
+---------+--------------------+------------+
| node_id | memory_type        | total      |
+---------+--------------------+------------+
|       5 | Data memory        | 1073741824 |
|       5 | Index memory       | 1074003968 |
|       5 | Long message buffer |   67108864 |
|       6 | Data memory        | 1073741824 |
```

```
|       6 | Index memory        | 1074003968 |
|       6 | Long message buffer |   67108864 |
+---------+---------------------+------------+
6 rows in set (0.00 sec)
```

In this case, the `total` column values for index memory are slightly higher than the value set of `IndexMemory` due to internal rounding.

For the `used_pages` and `total_pages` columns, resources are measured in pages, which are 32K in size for `DataMemory` and 8K for `IndexMemory`. For long message buffer memory, the page size is 256 bytes.

22.5.10.27 The ndbinfo memory_per_fragment Table

The `memory_per_fragment` table provides information about the usage of memory by individual fragments.

The following table provides information about the columns in the `memory_per_fragment` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.390 Columns of the memory_per_fragment table

Column Name	Type	Description
fq_name	string	Name of this fragment
parent_fq_name	string	Name of this fragment's parent
type	string	Type of object; see text for possible values
table_id	integer	Table ID for this table
node_id	integer	Node ID for this node
block_instance	integer	Kernel block instance ID
fragment_num	integer	Fragment ID (number)
fixed_elem_alloc_bytes	integer	Number of bytes allocated for fixed-sized elements
fixed_elem_free_bytes	integer	Free bytes remaining in pages allocated to fixed-size elements
fixed_elem_size_bytes	integer	Length of each fixed-size element in bytes
fixed_elem_count	integer	Number of fixed-size elements
fixed_elem_free_count	decimal	Number of free rows for fixed-size elements
var_elem_alloc_bytes	integer	Number of bytes allocated for variable-size elements
var_elem_free_bytes	integer	Free bytes remaining in pages allocated to variable-size elements
var_elem_count	integer	Number of variable-size elements
hash_index_alloc_bytes	integer	Number of bytes allocated to hash indexes

The `type` column from this table shows the dictionary object type used for this fragment (`Object::Type`, in the NDB API), and can take any one of the values shown in the following list:

- System table
- User table
- Unique hash index
- Hash index

- Unique ordered index
- Ordered index
- Hash index trigger
- Subscription trigger
- Read only constraint
- Index trigger
- Reorganize trigger
- Tablespace
- Log file group
- Data file
- Undo file
- Hash map
- Foreign key definition
- Foreign key parent trigger
- Foreign key child trigger
- Schema transaction

You can also obtain this list by executing `SELECT * FROM ndbinfo.dict_obj_types` in the `mysql` client.

The `block_instance` column provides the NDB kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

22.5.10.28 The ndbinfo nodes Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The following table provides information about the columns in the `nodes` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.391 Columns of the nodes table

Column Name	Type	Description
`node_id`	integer	The data node's unique node ID in the cluster.
`uptime`	integer	Time since the node was last started, in seconds.
`status`	string	Current status of the data node; see text for possible values.
`start_phase`	integer	If the data node is starting, the current start phase.
`config_generation`	integer	The version of the cluster configuration file in use on this data node.

The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a `BIGINT` value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmtd` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a nonzero value.

The `status` column shows the node's current status. This is one of: `NOTHING`, `CMVMI`, `STARTING`, `STARTED`, `SINGLEUSER`, `STOPPING_1`, `STOPPING_2`, `STOPPING_3`, or `STOPPING_4`. When the status is `STARTING`, you can see the current start phase in the `start_phase` column (see later in this section). `SINGLEUSER` is displayed in the `status` column for all data nodes when the cluster is in single user mode (see Section 22.5.8, “NDB Cluster Single User Mode”). Seeing one of the `STOPPING` states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state; for example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as `STOPPING_2` before the status changes to `SINGLEUSER`.

The `start_phase` column uses the same range of values as those used in the output of the `ndb_mgm` client *`node_id`* `STATUS` command (see Section 22.5.2, “Commands in the NDB Cluster Management Client”). If the node is not currently starting, then this column shows `0`. For a listing of NDB Cluster start phases with descriptions, see Section 22.5.1, “Summary of NDB Cluster Start Phases”.

The `config_generation` column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make changes in configuration parameters. For example, from the output of the following `SELECT` statement, you can see that node 3 is not yet using the latest version of the cluster configuration (`6`) although nodes 1, 2, and 4 are doing so:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  10462 | STARTED |           0 |                 6 |
|       2 |  10460 | STARTED |           0 |                 6 |
|       3 |  10457 | STARTED |           0 |                 5 |
|       4 |  10455 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
2 rows in set (0.04 sec)
```

Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

Nodes that are stopped are not accounted for in this table. Suppose that you have an NDB Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  11776 | STARTED |           0 |                 6 |
|       2 |  11774 | STARTED |           0 |                 6 |
|       3 |  11771 | STARTED |           0 |                 6 |
|       4 |  11769 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
4 rows in set (0.04 sec)
```

If you shut down one of the nodes, only the nodes that are still running are represented in the output of this `SELECT` statement, as shown here:

```
ndb_mgm> 2 STOP
Node 2: Node shutdown initiated
```

```
Node 2: Node shutdown completed.
Node 2 has shutdown.
```

```
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  11807 | STARTED |           0 |                 6 |
|       3 |  11802 | STARTED |           0 |                 6 |
|       4 |  11800 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
3 rows in set (0.02 sec)
```

22.5.10.29 The ndbinfo operations_per_fragment Table

The `operations_per_fragment` table provides information about the operations performed on individual fragments and fragment replicas, as well as about some of the results from these operations.

The following table provides information about the columns in the `operations_per_fragment` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.392 Columns of the operations_per_fragment table

Column Name	Type	Description
fq_name	string	Name of this fragment
parent_fq_name	string	Name of this fragment's parent
type	string	Type of object; see text for possible values
table_id	integer	Table ID for this table
node_id	integer	Node ID for this node
block_instance	integer	Kernel block instance ID
fragment_num	integer	Fragment ID (number)
tot_key_reads	integer	Total number of key reads for this fragment replica
tot_key_inserts	integer	Total number of key inserts for this fragment replica
tot_key_updates	integer	total number of key updates for this fragment replica
tot_key_writes	integer	Total number of key writes for this fragment replica
tot_key_deletes	integer	Total number of key deletes for this fragment replica
tot_key_refs	integer	Number of key operations refused
tot_key_attrinfo_bytes	integer	Total size of all `attrinfo` attributes
tot_key_keyinfo_bytes	integer	Total size of all `keyinfo` attributes
tot_key_prog_bytes	integer	Total size of all interpreted programs carried by `attrinfo` attributes
tot_key_inst_exec	integer	Total number of instructions executed by interpreted programs for key operations
tot_key_bytes_returned	integer	Total size of all data and metadata returned from key read operations
tot_frag_scans	integer	Total number of scans performed on this fragment replica

Column Name	Type	Description
tot_scan_rows_examined	integer	Total number of rows examined by scans
tot_scan_rows_returned	integer	Total number of rows returned to client
tot_scan_bytes_returned	integer	Total size of data and metadata returned to the client
tot_scan_prog_bytes	integer	Total size of interpreted programs for scan operations
tot_scan_bound_bytes	integer	Total size of all bounds used in ordered index scans
tot_scan_inst_exec	integer	Total number of instructions executed for scans
tot_qd_frag_scans	integer	Number of times that scans of this fragment replica have been queued
conc_frag_scans	integer	Number of scans currently active on this fragment replica (excluding queued scans)
conc_qd_frag_scans	integer	Number of scans currently queued for this fragment replica
tot_commits	integer	Total number of row changes committed to this fragment replica

The `fq_name` contains the fully qualified name of the schema object to which this fragment replica belongs. This currently has the following formats:

- Base table: - *`DbName`*`/def/`*`TblName`*
- `BLOB` table: - *`DbName`*`/def/NDB$BLOB_`*`BaseTblId_ColNo`*
- Ordered index: - `sys/def/`*`BaseTblId/IndexName`*
- Unique index: - `sys/def/`*`BaseTblId/IndexName`*`$unique`

The `$unique` suffix shown for unique indexes is added by `mysqld`; for an index created by a different NDB API client application, this may differ, or not be present.

The syntax just shown for fully qualified object names is an internal interface which is subject to change in future releases.

Consider a table `t1` created and modified by the following SQL statements:

```
CREATE DATABASE mydb;

USE mydb;

CREATE TABLE t1 (
  a INT NOT NULL,
  b INT NOT NULL,
  t TEXT NOT NULL,
  PRIMARY KEY (b)
) ENGINE=ndbcluster;

CREATE UNIQUE INDEX ix1 ON t1(b) USING HASH;
```

If `t1` is assigned table ID 11, this yields the `fq_name` values shown here:

- Base table: `mydb/def/t1`
- `BLOB` table: `mydb/def/NDB$BLOB_11_2`
- Ordered index (primary key): `sys/def/11/PRIMARY`

- Unique index: `sys/def/11/ix1$unique`

For indexes or `BLOB` tables, the `parent_fq_name` column contains the `fq_name` of the corresponding base table. For base tables, this column is always `NULL`.

The `type` column shows the schema object type used for this fragment, which can take any one of the values `System table`, `User table`, `Unique hash index`, or `Ordered index`. `BLOB` tables are shown as `User table`.

The `table_id` column value is unique at any given time, but can be reused if the corresponding object has been deleted. The same ID can be seen using the `ndb_show_tables` utility.

The `block_instance` column shows which LDM instance this fragment replica belongs to. You can use this to obtain information about specific threads from the `threadblocks` table. The first such instance is always numbered 0.

Since there are typically two replicas, and assuming that this is so, each `fragment_num` value should appear twice in the table, on two different data nodes from the same node group.

Since `NDB` does not use single-key access for ordered indexes, the counts for `tot_key_reads`, `tot_key_inserts`, `tot_key_updates`, `tot_key_writes`, and `tot_key_deletes` are not incremented by ordered index operations.

Note

When using `tot_key_writes`, you should keep in mind that a write operation in this context updates the row if the key exists, and inserts a new row otherwise. (One use of this is in the `NDB` implementation of the `REPLACE` SQL statement.)

The `tot_key_refs` column shows the number of key operations refused by the LDM. Generally, such a refusal is due to duplicate keys (inserts), `Key not found` errors (updates, deletes, and reads), or the operation was rejected by an interpreted program used as a predicate on the row matching the key.

The `attrinfo` and `keyinfo` attributes counted by the `tot_key_attrinfo_bytes` and `tot_key_keyinfo_bytes` columns are attributes of an `LQHKEYREQ` signal (see The NDB Communication Protocol) used to initiate a key operation by the LDM. An `attrinfo` typically contains tuple field values (inserts and updates) or projection specifications (for reads); `keyinfo` contains the primary or unique key needed to locate a given tuple in this schema object.

The value shown by `tot_frag_scans` includes both full scans (that examine every row) and scans of subsets. Unique indexes and `BLOB` tables are never scanned, so this value, like other scan-related counts, is 0 for fragment replicas of these.

`tot_scan_rows_examined` may display less than the total number of rows in a given fragment replica, since ordered index scans can limited by bounds. In addition, a client may choose to end a scan before all potentially matching rows have been examined; this occurs when using an SQL statement containing a `LIMIT` or `EXISTS` clause, for example. `tot_scan_rows_returned` is always less than or equal to `tot_scan_rows_examined`.

`tot_scan_bytes_returned` includes, in the case of pushed joins, projections returned to the `DBSPJ` block in the NDB kernel.

`tot_qd_frag_scans` can be effected by the setting for the `MaxParallelScansPerFragment` data node configuration parameter, which limits the number of scans that may execute concurrently on a single fragment replica.

22.5.10.30 The ndbinfo processes Table

This table contains information about NDB Cluster node processes; each node is represented by the row in the table. Only nodes that are connected to the cluster are shown in this table. You can obtain

information about nodes that are configured but not connected to the cluster from the `nodes` and `config_nodes` tables.

The following table provides information about the columns in the `processes` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.393 Columns of the nodes table

Column Name	Type	Description
`node_id`	integer	The node's unique node ID in the cluster
`node_type`	string	Type of node (management, data, or API node; see text)
`node_version`	string	Version of the `NDB` software program running on this node.
`process_id`	integer	This node's process ID
`angel_process_id`	integer	Process ID of this node's angel process
`process_name`	string	Name of the executable
`service_URI`	string	Service URI of this node (see text)

`node_id` is the ID assigned to this node in the cluster.

The `node_type` column displays one of the following three values:

- `MGM`: Management node.
- `NDB`: Data node.
- `API`: API or SQL node.

For an executable shipped with the NDB Cluster distribution, `node_version` shows the software Cluster version string, such as `8.0.16-ndb-8.0.16`.

`process_id` is the node executable's process ID as shown by the host operating system using a process display application such as `top` on Linux, or the Task Manager on Windows platforms.

`angel_process_id` is the system process ID for the node's angel process, which ensures that a data node or SQL is automatically restarted in cases of failures. For management nodes and API nodes other than SQL nodes, the value of this column is `NULL`.

The `process_name` column shows the name of the running executable. For management nodes, this is `ndb_mgmd`. For data nodes, this is `ndbd` (single-threaded) or `ndbmtd` (multithreaded). For SQL nodes, this is `mysqld`. For other types of API nodes, it is the name of the executable program connected to the cluster; NDB API applications can set a custom value for this using `Ndb_cluster_connection::set_name()`.

`service_URI` shows the service network address. For management nodes and data nodes, the scheme used is `ndb://`. For SQL nodes, this is `mysql://`. By default, API nodes other than SQL nodes use `ndb://` for the scheme; NDB API applications can set this to a custom value using `Ndb_cluster_connection::set_service_uri()`. regardless of the node type, the scheme is followed by the IP address used by the NDB transporter for the node in question. For management nodes and SQL nodes, this address includes the port number (usually 1186 for management nodes and 3306 for SQL nodes). If the SQL node was started with `--bind-address`, this address is used instead of the transporter address, unless the bind address is set to `*`, `0.0.0.0`, or `::`.

Additional path information may be included in the `service_URI` value for an SQL node reflecting various configuration options; for example, `mysql://198.51.100.3/tmp/mysql.sock` indicates that the SQL node was started with `--skip-networking`, and `mysql://198.51.100.3:3306/?server-id=1` shows that replication is enabled for this SQL node.

22.5.10.31 The ndbinfo resources Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as *super-pools*.

The following table provides information about the columns in the `resources` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.394 Columns of the resources table

Column Name	Type	Description
`node_id`	integer	The unique node ID of this data node.
`resource_name`	string	Name of the resource; see text.
`reserved`	integer	The amount reserved for this resource.
`used`	integer	The amount actually used by this resource.
`max`	integer	The maximum amount of this resource used, since the node was last started.

The `resource_name` can be one of the names shown in the following table:

Table 22.395 ndbinfo.resources table resource names and descriptions

Resource name	Description
`RESERVED`	Reserved by the system; cannot be overridden.
`DISK_OPERATIONS`	If a log file group is allocated, the size of the undo log buffer is used to set the size of this resource. This resource is used only to allocate the undo log buffer for an undo log file group; there can only be one such group. Overallocation occurs as needed by `CREATE LOGFILE GROUP`.
`DISK_RECORDS`	Records allocated for Disk Data operations.
`DATA_MEMORY`	Used for main memory tuples, indexes, and hash indexes. Sum of DataMemory and IndexMemory, plus 8 pages of 32 KB each if IndexMemory has been set. Cannot be overallocated.
`JOBBUFFER`	Used for allocating job buffers by the NDB scheduler; cannot be overallocated. This is approximately 2 MB per thread plus a 1 MB buffer in both directions for all threads that can communicate. For large configurations this consume several GB.
`FILE_BUFFERS`	Used by the redo log handler in the `DBLQH` kernel block; cannot be overallocated. Size is `NoOfFragmentLogParts` * `RedoBuffer`, plus 1 MB per log file part.
`TRANSPORTER_BUFFERS`	Used for send buffers by `ndbmtd`; the sum of `TotalSendBufferMemory` and `ExtraSendBufferMemory`. This resource that can be overallocated by up to 25 percent. `TotalSendBufferMemory` is calculated by summing the send buffer memory per node, the default value of which is 2 MB. Thus, in a system having four data nodes and eight API nodes, the data nodes have 12 * 2 MB send buffer memory. `ExtraSendBufferMemory` is used by `ndbmtd` and amounts to 2 MB extra memory per thread. Thus, with 4 LDM threads, 2 TC threads, 1 main thread, 1 replication thread, and 2 receive threads, `ExtraSendBufferMemory` is 10 * 2 MB. Overallocation of this resource can be performed by setting the `SharedGlobalMemory` data node configuration parameter.
`DISK_PAGE_BUFFER`	Used for the disk page buffer; determined by the `DiskPageBufferMemory` configuration parameter. Cannot be overallocated.

Resource name	Description
QUERY_MEMORY	Used by the DBSPJ kernel block.
SCHEMA_TRANS_MEMORY	Minimum is 2 MB; can be overallocated to use any remaining available memory.

22.5.10.32 The ndbinfo restart_info Table

The restart_info table contains information about node restart operations. Each entry in the table corresponds to a node restart status report in real time from a data node with the given node ID. Only the most recent report for any given node is shown.

The following table provides information about the columns in the restart_info table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.396 Columns of the restart_info table

Column Name	Type	Description
node_id	integer	Node ID in the cluster
node_restart_status	VARCHAR(256)	Node status; see text for values. Each of these corresponds to a possible value of node_restart_status_int.
node_restart_status_int	integer	Node status code; see text for values.
secs_to_complete_node_failure	integer	Time in seconds to complete node failure handling
secs_to_allocate_node_id	integer	Time in seconds from node failure completion to allocation of node ID
secs_to_include_in_heartbeat_protocol	integer	Time in seconds from allocation of node ID to inclusion in heartbeat protocol
secs_until_wait_for_ndbcntr_master	integer	Time in seconds from being included in heartbeat protocol until waiting for NDBCNTR master began
secs_wait_for_ndbcntr_master	integer	Time in seconds spent waiting to be accepted by NDBCNTR master for starting
secs_to_get_start_permitted	integer	Time in seconds elapsed from receiving of permission for start from master until all nodes have accepted start of this node
secs_to_wait_for_lcp_for_copy_meta_data	integer	Time in seconds spent waiting for LCP completion before copying meta data
secs_to_copy_meta_data	integer	Time in seconds required to copy metadata from master to newly starting node
secs_to_include_node	integer	Time in seconds waited for GCP and inclusion of all nodes into protocols
secs_starting_node_to_request_local_recovery	integer	Time in seconds that the node just starting spent waiting to request local recovery
secs_for_local_recovery	integer	Time in seconds required for local recovery by node just starting
secs_restore_fragments	integer	Time in seconds required to restore fragments from LCP files
secs_undo_disk_data	integer	Time in seconds required to execute undo log on disk data part of records

Column Name	Type	Description
secs_exec_redo_log	integer	Time in seconds required to execute redo log on all restored fragments
secs_index_rebuild	integer	Time in seconds required to rebuild indexes on restored fragments
secs_to_synchronize_starting_node	integer	Time in seconds required to synchronize starting node from live nodes
secs_wait_lcp_for_restart	integer	Time in seconds required for LCP start and completion before restart was completed
secs_wait_subscription_handover	integer	Time in seconds spent waiting for handover of replication subscriptions
total_restart_secs	integer	Total number of seconds from node failure until node is started again

Defined values for node_restart_status_int and corresponding status names and messages (node_restart_status) are shown in the following table:

Table 22.397 Status codes and messages used in the restart_info table

Column Name	Type	Description
0	ALLOCATED_NODE_ID	Allocated node id
1	INCLUDED_IN_HB_PROTOCOL	Included in heartbeat protocol
2	NDBCNTR_START_WAIT	Wait for NDBCNTR master to permit us to start
3	NDBCNTR_STARTED	NDBCNTR master permitted us to start
4	START_PERMITTED	All nodes permitted us to start
5	WAIT_LCP_TO_COPY_DICT	Wait for LCP completion to start copying metadata
6	COPY_DICT_TO_STARTING_NODE	Copying metadata to starting node
7	INCLUDE_NODE_IN_LCP_AND_GCP	Include node in LCP and GCP protocols
8	LOCAL_RECOVERY_STARTED	Restore fragments ongoing
9	COPY_FRAGMENTS_STARTED	Synchronizing starting node with live nodes
10	WAIT_LCP_FOR_RESTART	Wait for LCP to ensure durability
11	WAIT_SUMA_HANDOVER	Wait for handover of subscriptions
12	RESTART_COMPLETED	Restart completed
13	NODE_FAILED	Node failed, failure handling in progress
14	NODE_FAILURE_COMPLETED	Node failure handling completed
15	NODE_GETTING_PERMIT	All nodes permitted us to start
16	NODE_GETTING_INCLUDED	Include node in LCP and GCP protocols
17	NODE_GETTING_SYNCHED	Synchronizing starting node with live nodes
18	NODE_GETTING_LCP_WAITED	[none]
19	NODE_ACTIVE	Restart completed

Column Name	Type	Description
20	NOT_DEFINED_IN_CLUSTER	[none]
21	NODE_NOT_RESTARTED_YET	Initial state

Status numbers 0 through 12 apply on master nodes only; the remainder of those shown in the table apply to all restarting data nodes. Status numbers 13 and 14 define node failure states; 20 and 21 occur when no information about the restart of a given node is available.

See also Section 22.5.1, “Summary of NDB Cluster Start Phases”.

22.5.10.33 The ndbinfo server_locks Table

The `server_locks` table is similar in structure to the `cluster_locks` table, and provides a subset of the information found in the latter table, but which is specific to the SQL node (MySQL server) where it resides. (The `cluster_locks` table provides information about all locks in the cluster.) More precisely, `server_locks` contains information about locks requested by threads belonging to the current `mysqld` instance, and serves as a companion table to `server_operations`. This may be useful for correlating locking patterns with specific MySQL user sessions, queries, or use cases.

The following table provides information about the columns in the `server_locks` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.398 Columns of the server_locks table

Column Name	Type	Description
`mysql_connection_id`	integer	MySQL connection ID
`node_id`	integer	ID of reporting node
`block_instance`	integer	ID of reporting LDM instance
`tableid`	integer	ID of table containing this row
`fragmentid`	integer	ID of fragment containing locked row
`rowid`	integer	ID of locked row
`transid`	integer	Transaction ID
`mode`	string	Lock request mode
`state`	string	Lock state
`detail`	string	Whether this is first holding lock in row lock queue
`op`	string	Operation type
`duration_millis`	integer	Milliseconds spent waiting or holding lock
`lock_num`	integer	ID of lock object
`waiting_for`	integer	Waiting for lock with this ID

The `mysql_connection_id` column shows the MySQL connection or thread ID as shown by `SHOW PROCESSLIST`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The `tableid` is assigned to the table by `NDB`; the same ID is used for this table in other `ndbinfo` tables, as well as in the output of `ndb_show_tables`.

The transaction ID shown in the `transid` column is the identifier generated by the NDB API for the transaction requesting or holding the current lock.

The `mode` column shows the lock mode, which is always one of `S` (shared lock) or `X` (exclusive lock). If a transaction has an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The `state` column shows the lock state. Its value is always one of `H` (holding) or `W` (waiting). A waiting lock request waits for a lock held by a different transaction.

The `detail` column indicates whether this lock is the first holding lock in the affected row's lock queue, in which case it contains a `*` (asterisk character); otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The `op` column shows the type of operation requesting the lock. This is always one of the values `READ`, `INSERT`, `UPDATE`, `DELETE`, `SCAN`, or `REFRESH`.

The `duration_millis` column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (`lockid` column) is unique to this node and block instance.

If the `lock_state` column's value is `W`, this lock is waiting to be granted, and the `waiting_for` column shows the lock ID of the lock object this request is waiting for. Otherwise, `waiting_for` is empty. `waiting_for` can refer only to locks on the same row (as identified by `node_id`, `block_instance`, `tableid`, `fragmentid`, and `rowid`).

22.5.10.34 The ndbinfo server_operations Table

The `server_operations` table contains entries for all ongoing `NDB` operations that the current SQL node (MySQL Server) is currently involved in. It effectively is a subset of the `cluster_operations` table, in which operations for other SQL and API nodes are not shown.

The following table provides information about the columns in the `server_operations` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.399 Columns of the server_operations table

Column Name	Type	Description
`mysql_connection_id`	integer	MySQL Server connection ID
`node_id`	integer	Node ID
`block_instance`	integer	Block instance
`transid`	integer	Transaction ID
`operation_type`	string	Operation type (see text for possible values)
`state`	string	Operation state (see text for possible values)
`tableid`	integer	Table ID
`fragmentid`	integer	Fragment ID
`client_node_id`	integer	Client node ID
`client_block_ref`	integer	Client block reference
`tc_node_id`	integer	Transaction coordinator node ID
`tc_block_no`	integer	Transaction coordinator block number
`tc_block_instance`	integer	Transaction coordinator block instance

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The transaction ID (`transid`) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dblqh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an `NDB` table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` and `tc_block_instance` column provide NDB kernel block instance numbers. You can use these to obtain information about specific threads from the `threadblocks` table.

22.5.10.35 The ndbinfo server_transactions Table

The `server_transactions` table is subset of the `cluster_transactions` table, but includes only those transactions in which the current SQL node (MySQL Server) is a participant, while including the relevant connection IDs.

The following table provides information about the columns in the `server_transactions` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.400 Columns of the server_transactions table

Column Name	Type	Description
`mysql_connection_id`	integer	MySQL Server connection ID
`node_id`	integer	Transaction coordinator node ID
`block_instance`	integer	Transaction coordinator block instance
`transid`	integer	Transaction ID
`state`	string	Operation state (see text for possible values)
`count_operations`	integer	Number of stateful operations in the transaction
`outstanding_operations`	integer	Operations still being executed by local data management layer (LQH blocks)
`inactive_seconds`	integer	Time spent waiting for API

Column Name	Type	Description
client_node_id	integer	Client node ID
client_block_ref	integer	Client block reference

The mysql_connection_id is the same as the connection or session ID shown in the output of SHOW PROCESSLIST. It is obtained from the INFORMATION_SCHEMA table NDB_TRANSID_MYSQL_CONNECTION_MAP.

block_instance refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the threadblocks table.

The transaction ID (transid) is a unique 64-bit number which can be obtained using the NDB API's getTransactionId() method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The state column can have any one of the values CS_ABORTING, CS_COMMITTING, CS_COMMIT_SENT, CS_COMPLETE_SENT, CS_COMPLETING, CS_CONNECTED, CS_DISCONNECTED, CS_FAIL_ABORTED, CS_FAIL_ABORTING, CS_FAIL_COMMITTED, CS_FAIL_COMMITTING, CS_FAIL_COMPLETED, CS_FAIL_PREPARED, CS_PREPARE_TO_COMMIT, CS_RECEIVING, CS_REC_COMMITTING, CS_RESTART, CS_SEND_FIRE_TRIG_REQ, CS_STARTED, CS_START_COMMITTING, CS_START_SCAN, CS_WAIT_ABORT_CONF, CS_WAIT_COMMIT_CONF, CS_WAIT_COMPLETE_CONF, CS_WAIT_FIRE_TRIG_REQ. (If the MySQL Server is running with ndbinfo_show_hidden enabled, you can view this list of states by selecting from the ndb$dbtc_apiconnect_state table, which is normally hidden.)

In client_node_id and client_block_ref, client refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The block_instance column provides the DBTC kernel block instance number. You can use this to obtain information about specific threads from the threadblocks table.

22.5.10.36 The ndbinfo table_distribution_status Table

The table_distribution_status table provides information about the progress of table distribution for NDB tables.

The following table provides information about the columns in table_distribution_status. For each column, the table shows the name, data type, and a brief description.

Table 22.401 Columns of the table_distribution_status table

Column Name	Type	Description
node_id	integer	Node id
table_id	integer	Table ID
tab_copy_status	string	Status of copying of table distribution data to disk; one of IDLE, SR_PHASE1_READ_PAGES, SR_PHASE2_READ_TABLE, SR_PHASE3_COPY_TABLE, REMOVE_NODE, LCP_READ_TABLE, COPY_TAB_REQ, COPY_NODE_STATE, ADD_TABLE_MASTER, ADD_TABLE_SLAVE, INVALIDATE_NODE_LCP, ALTER_TABLE, COPY_TO_SAVE, or GET_TABINFO
tab_update_status	string	Status of updating of table distribution data; one of IDLE, LOCAL_CHECKPOINT, LOCAL_CHECKPOINT_QUEUED,

Column Name	Type	Description
		REMOVE_NODE, COPY_TAB_REQ, ADD_TABLE_MASTER, ADD_TABLE_SLAVE, INVALIDATE_NODE_LCP, or CALLBACK
tab_lcp_status	string	Status of table LCP; one of ACTIVE (waiting for local checkpoint to be performed), WRITING_TO_FILE (checkpoint performed but not yet written to disk), or COMPLETED (checkpoint performed and persisted to disk)
tab_status	string	Table internal status; one of ACTIVE (table exists), CREATING (table is being created), or DROPPING (table is being dropped)
tab_storage	string	Table recoverability; one of NORMAL (fully recoverable with redo logging and checkpointing), NOLOGGING (recoverable from node crash, empty following cluster crash), or TEMPORARY (not recoverable)
tab_partitions	integer	Number of partitions in table
tab_fragments	integer	Number of fragments in table; normally same as tab_partitions; for fully replicated tables equal to tab_partitions * [number of node groups]
current_scan_count	integer	Current number of active scans
scan_count_wait	integer	Current number of scans waiting to be performed before ALTER TABLE can complete.
is_reorg_ongoing	integer	Whether table is currently being reorganized (1 if true)

22.5.10.37 The ndbinfo table_fragments Table

The table_fragments table provides information about the fragmentation, partitioning, distribution, and (internal) replication of NDB tables.

The following table provides information about the columns in table_fragments. For each column, the table shows the name, data type, and a brief description.

Table 22.402 Columns of the table_fragments table

Column Name	Type	Description
node_id	integer	Node ID (DIH master)
table_id	integer	Table ID
partition_id	integer	Partition ID
fragment_id	integer	Fragment ID (same as partition ID unless table is fully replicated)
partition_order	integer	Order of fragment in partition
log_part_id	integer	Log part ID of fragment
no_of_replicas	integer	Number of replicas
current_primary	integer	Current primary node ID
preferred_primary	integer	Preferred primary node ID
current_first_backup	integer	Current first backup node ID

Column Name	Type	Description
current_second_backup	integer	Current second backup node ID
current_third_backup	integer	Current third backup node ID
num_alive_replicas	integer	Current number of live replicas
num_dead_replicas	integer	Current number of dead replicas
num_lcp_replicas	integer	Number of replicas remaining to be checkpointed

22.5.10.38 The ndbinfo table_info Table

The table_info table provides information about logging, checkpointing, distribution, and storage options in effect for individual NDB tables.

The following table provides information about the columns in table_info. For each column, the table shows the name, data type, and a brief description.

Table 22.403 Columns of the table_info table

Column Name	Type	Description
table_id	integer	Table ID
logged_table	integer	Whether table is logged (1) or not (0)
row_contains_gci	integer	Whether table rows contain GCI (1 true, 0 false)
row_contains_checksum	integer	Whether table rows contain checksum (1 true, 0 false)
read_backup	integer	If backup replicas are read this is 1, otherwise 0
fully_replicated	integer	If table is fully replicated this is 1, otherwise 0
storage_type	string	Table storage type; one of MEMORY or DISK
hashmap_id	integer	Hashmap ID
partition_balance	string	Partition balance (fragment count type) used for table; one of FOR_RP_BY_NODE, FOR_RA_BY_NODE, FOR_RP_BY_LDM, or FOR_RA_BY_LDM
create_gci	integer	GCI in which table was created

22.5.10.39 The ndbinfo table_replicas Table

The table_replicas table provides information about the copying, distribution, and checkpointing of NDB table fragments and fragment replicas.

The following table provides information about the columns in table_replicas. For each column, the table shows the name, data type, and a brief description.

Table 22.404 Columns of the table_replicas table

Column Name	Type	Description
node_id	integer	ID of the node from which data is fetched (DIH master)
table_id	integer	Table ID
fragment_id	integer	Fragment ID
initial_gci	integer	Initial GCI for table

Column Name	Type	Description
replica_node_id	integer	ID of node where replica is stored
is_lcp_ongoing	integer	Is 1 if LCP is ongoing on this fragment, 0 otherwise
num_crashed_replicas	integer	Number of crashed replica instances
last_max_gci_started	integer	Highest GCI started in most recent LCP
last_max_gci_completed	integer	Highest GCI completed in most recent LCP
last_lcp_id	integer	ID of most recent LCP
prev_lcp_id	integer	ID of previous LCP
prev_max_gci_started	integer	Highest GCI started in previous LCP
prev_max_gci_completed	integer	Highest GCI completed in previous LCP
last_create_gci	integer	Last Create GCI of last crashed replica instance
last_replica_gci	integer	Last GCI of last crashed replica instance
is_replica_alive	integer	1 if this replica is alive, 0 otherwise

22.5.10.40 The ndbinfo tc_time_track_stats Table

The tc_time_track_stats table provides time-tracking information obtained from the DBTC block (TC) instances in the data nodes, through API nodes access NDB. Each TC instance tracks latencies for a set of activities it undertakes on behalf of API nodes or other data nodes; these activities include transactions, transaction errors, key reads, key writes, unique index operations, failed key operations of any type, scans, failed scans, fragment scans, and failed fragment scans.

A set of counters is maintained for each activity, each counter covering a range of latencies less than or equal to an upper bound. At the conclusion of each activity, its latency is determined and the appropriate counter incremented. tc_time_track_stats presents this information as rows, with a row for each instance of the following:

- Data node, using its ID
- TC block instance
- Other communicating data node or API node, using its ID
- Upper bound value

Each row contains a value for each activity type. This is the number of times that this activity occurred with a latency within the range specified by the row (that is, where the latency does not exceed the upper bound).

The following table provides information about the columns in tc_time_track_stats. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.405 Columns of the tc_time_track_stats table

Column Name	Type	Description
node_id	integer	Requesting node ID
block_number	integer	TC block number
block_instance	integer	TC block instance number
comm_node_id	integer	Node ID of communicating API or data node
upper_bound	integer	Upper bound of interval (in microseconds)

Column Name	Type	Description
scans	integer	Based on duration of successful scans from opening to closing, tracked against the API or data nodes requesting them.
scan_errors	integer	Based on duration of failed scans from opening to closing, tracked against the API or data nodes requesting them.
scan_fragments	integer	Based on duration of successful fragment scans from opening to closing, tracked against the data nodes executing them
scan_fragment_errors	integer	Based on duration of failed fragment scans from opening to closing, tracked against the data nodes executing them
transactions	integer	Based on duration of successful transactions from beginning until sending of commit ACK, tracked against the API or data nodes requesting them. Stateless transactions are not included.
transaction_errors	integer	Based on duration of failing transactions from start to point of failure, tracked against the API or data nodes requesting them.
read_key_ops	integer	Based on duration of successful primary key reads with locks. Tracked against both the API or data node requesting them and the data node executing them.
write_key_ops	integer	Based on duration of successful primary key writes, tracked against both the API or data node requesting them and the data node executing them.
index_key_ops	integer	Based on duration of successful unique index key operations, tracked against both the API or data node requesting them and the data node executing reads of base tables.
key_op_errors	integer	Based on duration of all unsuccessful key read or write operations, tracked against both the API or data node requesting them and the data node executing them.

The block_instance column provides the DBTC kernel block instance number. You can use this together with the block name to obtain information about specific threads from the threadblocks table.

22.5.10.41 The ndbinfo threadblocks Table

The threadblocks table associates data nodes, threads, and instances of NDB kernel blocks.

The following table provides information about the columns in the threadblocks table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.406 Columns of the threadblocks table

Column Name	Type	Description
node_id	integer	Node ID

Column Name	Type	Description
thr_no	integer	Thread ID
block_name	string	Block name
block_instance	integer	Block instance number

The value of the block_name in this table is one of the values found in the block_name column when selecting from the ndbinfo.blocks table. Although the list of possible values is static for a given NDB Cluster release, the list may vary between releases.

The block_instance column provides the kernel block instance number.

22.5.10.42 The ndbinfo threads Table

The threads table provides information about threads running in the NDB kernel.

The following table provides information about the columns in the threads table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.407 Columns of the threads table

Column Name	Type	Description
node_id	integer	ID of the node where the thread is running
thr_no	integer	Thread ID (specific to this node)
thread_name	string	Thread name (type of thread)
thread_description	string	Thread (type) description

Sample output from a 2-node example cluster, including thread descriptions, is shown here:

```
mysql> SELECT * FROM threads;
+---------+--------+-------------+-----------------------------------------------------------------+
| node_id | thr_no | thread_name | thread_description                                              |
+---------+--------+-------------+-----------------------------------------------------------------+
|       5 |      0 | main        | main thread, schema and distribution handling                   |
|       5 |      1 | rep         | rep thread, asynch replication and proxy block handling         |
|       5 |      2 | ldm         | ldm thread, handling a set of data partitions                   |
|       5 |      3 | recv        | receive thread, performing receive and polling for new receives |
|       6 |      0 | main        | main thread, schema and distribution handling                   |
|       6 |      1 | rep         | rep thread, asynch replication and proxy block handling         |
|       6 |      2 | ldm         | ldm thread, handling a set of data partitions                   |
|       6 |      3 | recv        | receive thread, performing receive and polling for new receives |
+---------+--------+-------------+-----------------------------------------------------------------+
8 rows in set (0.01 sec)
```

22.5.10.43 The ndbinfo threadstat Table

The threadstat table provides a rough snapshot of statistics for threads running in the NDB kernel.

The following table provides information about the columns in the threadstat table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.408 Columns of the threadstat table

Column Name	Type	Description
node_id	integer	Node ID
thr_no	integer	Thread ID

Column Name	Type	Description
thr_nm	string	Thread name
c_loop	string	Number of loops in main loop
c_exec	string	Number of signals executed
c_wait	string	Number of times waiting for additional input
c_l_sent_prioa	integer	Number of priority A signals sent to own node
c_l_sent_priob	integer	Number of priority B signals sent to own node
c_r_sent_prioa	integer	Number of priority A signals sent to remote node
c_r_sent_priob	integer	Number of priority B signals sent to remote node
os_tid	integer	OS thread ID
os_now	integer	OS time (ms)
os_ru_utime	integer	OS user CPU time (µs)
os_ru_stime	integer	OS system CPU time (µs)
os_ru_minflt	integer	OS page reclaims (soft page faults)
os_ru_majflt	integer	OS page faults (hard page faults)
os_ru_nvcsw	integer	OS voluntary context switches
os_ru_nivcsw	integer	OS involuntary context switches

os_time uses the system gettimeofday() call.

The values of the os_ru_utime, os_ru_stime, os_ru_minflt, os_ru_majflt, os_ru_nvcsw, and os_ru_nivcsw columns are obtained using the system getrusage() call, or the equivalent.

Since this table contains counts taken at a given point in time, for best results it is necessary to query this table periodically and store the results in an intermediate table or tables. The MySQL Server's Event Scheduler can be employed to automate such monitoring. For more information, see Section 24.4, “Using the Event Scheduler”.

22.5.10.44 The ndbinfo transporters Table

This table contains information about NDB transporters.

The following table provides information about the columns in the transporters table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 22.409 Columns of the transporters table

Column Name	Type	Description
node_id	integer	This data node's unique node ID in the cluster
remote_node_id	integer	The remote data node's node ID
status	string	Status of the connection
remote_address	string	Name or IP address of the remote host
bytes_sent	integer	Number of bytes sent using this connection
bytes_received	integer	Number of bytes received using this connection

Column Name	Type	Description
connect_count	integer	Number of times connection established on this transporter
overloaded	boolean (0 or 1)	1 if this transporter is currently overloaded, otherwise 0
overload_count	integer	Number of times this transporter has entered overload state since connecting
slowdown	boolean (0 or 1)	1 if this transporter is in slowdown state, otherwise 0
slowdown_count	integer	Number of times this transporter has entered slowdown state since connecting

For each running data node in the cluster, the transporters table displays a row showing the status of each of that node's connections with all nodes in the cluster, *including itself*. This information is shown in the table's *status* column, which can have any one of the following values: CONNECTING, CONNECTED, DISCONNECTING, or DISCONNECTED.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status DISCONNECTED. Rows where the node_id is that of a data node which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the ndbinfo.nodes table.

The remote_address is the host name or address for the node whose ID is shown in the remote_node_id column. The bytes_sent from this node and bytes_received by this node are the numbers, respectively, of bytes sent and received by the node using this connection since it was established. For nodes whose status is CONNECTING or DISCONNECTED, these columns always display 0.

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the SHOW command in the ndb_mgm client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @10.100.10.1  (8.0.16-ndb-8.0.16, Nodegroup: 0, *)
id=2    @10.100.10.2  (8.0.16-ndb-8.0.16, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @10.100.10.10  (8.0.16-ndb-8.0.16)

[mysqld(API)]   2 node(s)
id=20   @10.100.10.20  (8.0.16-ndb-8.0.16)
id=21   @10.100.10.21  (8.0.16-ndb-8.0.16)
```

There are 10 rows in the transporters table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
    ->   FROM ndbinfo.transporters;
+---------+----------------+---------------+
| node_id | remote_node_id | status        |
+---------+----------------+---------------+
|       1 |              1 | DISCONNECTED  |
|       1 |              2 | CONNECTED     |
|       1 |             10 | CONNECTED     |
|       1 |             20 | CONNECTED     |
|       1 |             21 | CONNECTED     |
|       2 |              1 | CONNECTED     |
```

```
|       2 |              2 | DISCONNECTED  |
|       2 |             10 | CONNECTED     |
|       2 |             20 | CONNECTED     |
|       2 |             21 | CONNECTED     |
+---------+----------------+---------------+
10 rows in set (0.04 sec)
```

If you shut down one of the data nodes in this cluster using the command `2 STOP` in the `ndb_mgm` client, then repeat the previous query (again using the `mysql` client), this table now shows only 5 rows—1 row for each connection from the remaining management node to another node, including both itself and the data node that is currently offline—and displays `CONNECTING` for the status of each remaining connection to the data node that is currently offline, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
    ->   FROM ndbinfo.transporters;
+---------+----------------+--------------+
| node_id | remote_node_id | status       |
+---------+----------------+--------------+
|       1 |              1 | DISCONNECTED |
|       1 |              2 | CONNECTING   |
|       1 |             10 | CONNECTED    |
|       1 |             20 | CONNECTED    |
|       1 |             21 | CONNECTED    |
+---------+----------------+--------------+
5 rows in set (0.02 sec)
```

The `connect_count`, `overloaded`, `overload_count`, `slowdown`, and `slowdown_count` counters are reset on connection, and retain their values after the remote node disconnects. The `bytes_sent` and `bytes_received` counters are also reset on connection, and so retain their values following disconnection (until the next connection resets them).

The *overload* state referred to by the `overloaded` and `overload_count` columns occurs when this transporter's send buffer contains more than `OVerloadLimit` bytes (default is 80% of `SendBufferMemory`, that is, 0.8 * 2097152 = 1677721 bytes). When a given transporter is in a state of overload, any new transaction that tries to use this transporter fails with Error 1218 (`Send Buffers overloaded in NDB kernel`). This affects both scans and primary key operations.

The *slowdown* state referenced by the `slowdown` and `slowdown_count` columns of this table occurs when the transporter's send buffer contains more than 60% of the overload limit (equal to 0.6 * 2097152 = 1258291 bytes by default). In this state, any new scan using this transporter has its batch size reduced to minimize the load on the transporter.

Common causes of send buffer slowdown or overloading include the following:

- Data size, in particular the quantity of data stored in `TEXT` columns or `BLOB` columns (or both types of columns)
- Having a data node (ndbd or ndbmtd) on the same host as an SQL node that is engaged in binary logging
- Large number of rows per transaction or transaction batch
- Configuration issues such as insufficient `SendBufferMemory`
- Hardware issues such as insufficient RAM or poor network connectivity

See also Section 22.3.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

22.5.11 INFORMATION_SCHEMA Tables for NDB Cluster

Two `INFORMATION_SCHEMA` tables provide information that is of particular use when managing an NDB Cluster . The `FILES` table provides information about NDB Cluster Disk Data files. The

`ndb_transid_mysql_connection_map` table provides a mapping between transactions, transaction coordinators, and API nodes.

Additional statistical and other data about NDB Cluster transactions, operations, threads, blocks, and other aspects of performance can be obtained from the tables in the `ndbinfo` database. For information about these tables, see Section 22.5.10, “ndbinfo: The NDB Cluster Information Database”.

22.5.12 NDB Cluster Security Issues

This section discusses security considerations to take into account when setting up and running NDB Cluster.

Topics covered in this section include the following:

- NDB Cluster and network security issues
- Configuration issues relating to running NDB Cluster securely
- NDB Cluster and the MySQL privilege system
- MySQL standard security procedures as applicable to NDB Cluster

22.5.12.1 NDB Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to NDB Cluster. It is extremely important to remember that NDB Cluster “out of the box” is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster's efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes will effectively slow communications.

It is also true that no authentication is used for controlling API node access to an NDB Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

- SQL or API nodes using “free slots” created by empty `[mysqld]` or `[api]` sections in the `config.ini` file

  This means that, if there are any empty `[mysqld]` or `[api]` sections in the `config.ini` file, then any API nodes (including SQL nodes) that know the management server's host name (or IP address) and port can connect to the cluster and access its data without restriction. (See Section 22.5.12.2, “NDB Cluster and MySQL Privileges”, for more information about this and related issues.)

Note

You can exercise some control over SQL and API node access to the cluster by specifying a `HostName` parameter for all `[mysqld]` and `[api]` sections in the `config.ini` file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an `[api]` section containing its host name to the `config.ini` file.

More information is available elsewhere in this chapter about the `HostName` parameter. Also see Section 22.3.1, “Quick Test Setup of NDB Cluster”, for configuration examples using `HostName` with API nodes.

- Any `ndb_mgm` client

  This means that any cluster management client that is given the management server's host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as `ALL STOP` and `SHUTDOWN`.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

   We show an example of an NDB Cluster setup using such a physically segregated network here:

   Figure 22.27 NDB Cluster with Hardware Firewall

   
   This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a *network-based firewall*.

   This network setup is safest because no packets can reach the cluster's management or data nodes from outside the network—and none of the cluster's internal communications can reach the outside—without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

   Important

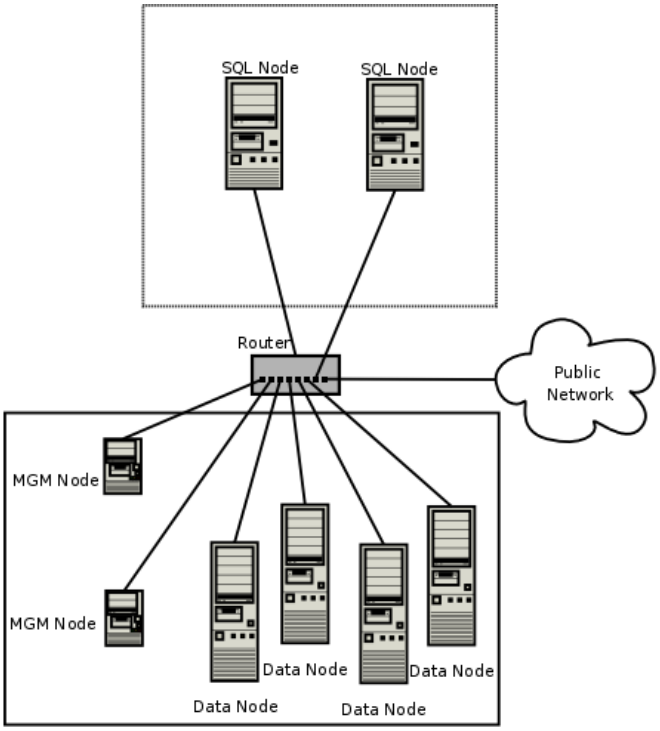
   With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See Section 6.1.3, “Making MySQL Secure Against Attackers”, for a description of techniques you can use to secure MySQL servers.

2. Using one or more software firewalls (also known as *host-based firewalls*) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

   The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for NDB Cluster is illustrated here:

Figure 22.28 NDB Cluster with Software Firewalls



Using this type of network setup means that there are two zones of NDB Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

Table 22.410 Node types in a host-based firewall cluster configuration

Node Type	Permitted Traffic
SQL or API node	• It originates from the IP address of a management or data node (using any TCP or UDP port). • It originates from within the network in which the cluster resides and is on the port that your application is using.
Data node or Management node	• It originates from the IP address of a management or data node (using any TCP or UDP port). • It originates from the IP address of an SQL or API node.

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. `iptables` is a very common and reliable firewall application, which is often used with `APF` as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to

implement an NDB Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

3. It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

   One possible network deployment of an NDB Cluster using hardware and software firewalls in combination is shown here:

   Figure 22.29 NDB Cluster with a Combination of Hardware and Software Firewalls

   In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because NDB Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

Note

If you wish to administer an NDB Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the Cluster's own local network.

Even though it is possible to do so in theory, it is *not* recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

22.5.12.2 NDB Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to NDB Cluster and the implications of this for keeping an NDB Cluster secure.

Standard MySQL privileges apply to NDB Cluster tables. This includes all MySQL privilege types (`SELECT` privilege, `UPDATE` privilege, `DELETE` privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the `mysql` system database. The SQL statements used to grant and revoke privileges on `NDB` tables, databases containing such tables, and columns within such tables are identical in all respects with the `GRANT` and `REVOKE` statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the `CREATE USER` and `DROP USER` statements.

It is important to keep in mind that, by default, the MySQL grant tables use the `MyISAM` storage engine. Because of this, those tables are not normally duplicated or shared among MySQL servers acting as SQL nodes in an NDB Cluster. In other words, changes in users and their privileges do not automatically propagate between SQL nodes by default. If you wish, you can enable automatic distribution of MySQL users and privileges across NDB Cluster SQL nodes; see Section 22.5.16, “Distributed MySQL Privileges for NDB Cluster”, for details.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for `NDB` tables on one SQL node from users that have privileges on another SQL node; (This is true even if you are not using automatic distribution of user privileges. The definitive example of this is the MySQL `root` account, which can perform any action on any database object. In combination with empty `[mysqld]` or `[api]` sections of the `config.ini` file, this account can be especially dangerous. To understand why, consider the following scenario:

- The `config.ini` file contains at least one empty `[mysqld]` or `[api]` section. This means that the NDB Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the NDB Cluster.
- There is no firewall, or the firewall fails to protect against access to the NDB Cluster from hosts external to the network.
- The host name or IP address of the NDB Cluster management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with `--ndbcluster --ndb-connectstring=`*`management_host`* and access this NDB Cluster. Using the MySQL `root` account, this person can then perform the following actions:

- Execute metadata statements such as `SHOW DATABASES` statement (to obtain a list of all `NDB` databases on the server) or `SHOW TABLES FROM` *`some_ndb_database`* statement to obtain a list of all `NDB` tables in a given database
- Run any legal MySQL statements on any of the discovered tables, such as:
  - `SELECT * FROM` *`some_table`* to read all the data from any table
  - `DELETE FROM` *`some_table`* to delete all the data from a table
  - `DESCRIBE` *`some_table`* or `SHOW CREATE TABLE` *`some_table`* to determine the table schema
  - `UPDATE` *`some_table`* `SET` *`column1 = some_value`* to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data

    More insidious variations might include statements like these:

    ```
    UPDATE some_table SET an_int_column = an_int_column + 1
    ```

or

```
UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
```

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than `NDB`, and so not visible to a “rogue” SQL node.

A user who can log in as `root` can also access the `INFORMATION_SCHEMA` database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in `INFORMATION_SCHEMA`.

It is also a very good idea to use different passwords for the `root` accounts on different NDB Cluster SQL nodes unless you are using distributed privileges.

In sum, you cannot have a safe NDB Cluster if it is directly accessible from outside your local network.

Important

Never leave the MySQL root account password empty. This is just as true when running MySQL as an NDB Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in an NDB Cluster.

If you wish to employ NDB Cluster's distributed privilege capabilities, you should not simply convert the system tables in the `mysql` database to use the `NDB` storage engine manually. Use the stored procedure provided for this purpose instead; see Section 22.5.16, “Distributed MySQL Privileges for NDB Cluster”.

Otherwise, if you need to synchronize `mysql` system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

Summary. The most important points to remember regarding the MySQL privilege system with regard to NDB Cluster are listed here:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.

2. You can distribute MySQL users and privileges among SQL nodes using the SQL script, and the stored procedures it contains, that are supplied for this purpose in the NDB Cluster distribution.

3. Once a MySQL user is granted privileges on an `NDB` table from one SQL node in an NDB Cluster, that user can “see” any data in that table regardless of the SQL node from which the data originated, even if you are not using privilege distribution.

22.5.12.3 NDB Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running NDB Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of an NDB Cluster. First and foremost, you should always run a MySQL Server as the `mysql` operating system user; this is no different from running MySQL in a standard (non-Cluster) environment. The `mysql` system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the `mysqld` process is running as the `mysql` operating system user by using the system command such as the one shown here:

```
shell> ps aux | grep mysql
root     10467  0.0  0.1   3616  1380 pts/3    S    11:53   0:00 \
  /bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql    10512  0.2  2.5  58528 26636 pts/3    Sl   11:53   0:00 \
  /usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql \
  --datadir=/usr/local/mysql/var --user=mysql --ndbcluster \
  --ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid \
  --log-error=/usr/local/mysql/var/mothra.err
jon      10579  0.0  0.0   2736   688 pts/0    S+   11:54   0:00 grep mysql
```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL data directory on this system (as set using the `--datadir` option for `mysqld`) is owned by the `mysql` user, and that the SQL node's `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the MySQL server process with `--user=mysql` on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

Important

Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see Section 22.5.12.2, “NDB Cluster and MySQL Privileges”), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```
shell> mysql -u root

mysql> UPDATE mysql.user
    ->     SET Password=PASSWORD('secure_password')
    ->     WHERE User='root';

mysql> DELETE FROM mysql.user
    ->     WHERE User='';

mysql> FLUSH PRIVILEGES;
```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting *all* MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

Note

Many of the NDB Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.

See Section 22.4, “NDB Cluster Programs”, for more information about these utilities.

22.5.13 NDB Cluster Disk Data Tables

NDB Cluster supports storing nonindexed columns of `NDB` tables on disk, rather than in RAM. Column data and logging metadata are kept in data files and undo log files, conceptualized as tablespaces

and log file groups, as described in the next section—see Section 22.5.13.1, “NDB Cluster Disk Data Objects”.

NDB Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see Disk Data Configuration Parameters, and Disk Data and GCP Stop errors.

The performance of an NDB Cluster that uses Disk Data storage can also be greatly improved by separating data node file systems from undo log files and tablespace data files, which can be done using symbolic links. For more information, see Section 22.5.13.2, “Using Symbolic Links with Disk Data Objects”.

22.5.13.1 NDB Cluster Disk Data Objects

NDB Cluster Disk Data storage is implemented using the following objects:

- *Tablespace*: Acts as containers for other Disk Data objects. A tablespace contains one or more data files and one or more undo log file groups.
- *Data file*: Stores column data. A data file is assigned directly to a tablespace.
- *Undo log file*: Contains undo information required for rolling back transactions. Assigned to an undo log file group.
- *log file group*: Contains one or more undo log files. Assigned to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the NDB Cluster `config.ini` file, and where `node_id` is the data node's node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

Undo log files are used only by Disk Data tables, and are not needed or used by `NDB` tables that are stored in memory only.

NDB Cluster tablespaces and log file groups are not implemented as files.

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named `dd1`.

Assuming that you have already set up an NDB Cluster with all nodes (including management and SQL nodes), the basic steps for creating an NDB Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an *undofile*).
2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.
3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the `mysql` client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named `lg_1` using `CREATE LOGFILE GROUP`. This log file group is to be made up of two undo log files, which we name `undo_1.log` and `undo_2.log`, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add `undo_1.log` to `lg_1` in this `CREATE LOGFILE GROUP` statement:

```
CREATE LOGFILE GROUP lg_1
```

```
    ADD UNDOFILE 'undo_1.log'
    INITIAL_SIZE 16M
    UNDO_BUFFER_SIZE 2M
    ENGINE NDBCLUSTER;
```

To add `undo_2.log` to the log file group, use the following `ALTER LOGFILE GROUP` statement:

```
ALTER LOGFILE GROUP lg_1
    ADD UNDOFILE 'undo_2.log'
    INITIAL_SIZE 12M
    ENGINE NDBCLUSTER;
```

Some items of note:

- The `.log` file extension used here is not required. We employ it merely to make the log files easily recognizable.
- Every `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statement must include an `ENGINE` option. The only permitted values for this option are `NDBCLUSTER` and `NDB`.

Important

There can exist at most one log file group in the same NDB Cluster at any given time.

- When you add an undo log file to a log file group using `ADD UNDOFILE 'filename'`, a file with the name *`filename`* is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where *`node_id`* is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the `ALTER LOGFILE GROUP` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `undo_2.log` and each file is 12 MB in size.
- `UNDO_BUFFER_SIZE` is limited by the amount of system memory available.
- See Section 13.1.16, “CREATE LOGFILE GROUP Syntax”, and Section 13.1.6, “ALTER LOGFILE GROUP Syntax”, for more information about these statements.

2. Now we can create a tablespace—an abstract container for files used by Disk Data tables to store data. A tablespace is associated with a particular log file group; when creating a new tablespace, you must specify the log file group it uses for undo logging. You must also specify at least one data file; you can add more data files to the tablespace after the tablespace is created. It is also possible to drop data files from a tablespace (see example later in this section).

   Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its log file group. We want the tablespace to contain two data files, named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for `INITIAL_SIZE` is 128 MB.) We can do this using two SQL statements, as shown here:

```
CREATE TABLESPACE ts_1
    ADD DATAFILE 'data_1.dat'
    USE LOGFILE GROUP lg_1
    INITIAL_SIZE 32M
    ENGINE NDBCLUSTER;

ALTER TABLESPACE ts_1
    ADD DATAFILE 'data_2.dat'
    INITIAL_SIZE 48M;
```

   The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

Some items of note:

- As is the case with the `.log` file extension used in this example for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition.
- When you add a data file to a tablespace using `ADD DATAFILE 'filename'`, a file with the name *`filename`* is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where *`node_id`* is the node ID of the data node. Each data file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the `ALTER TABLESPACE` statement just shown creates 4 data files, 1 each in the data directory of each of the 4 data nodes; each of these files is named `data_2.dat` and each file is 48 MB in size.
- `CREATE TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. For `ALTER TABLESPACE`, an `ENGINE` clause is accepted but is deprecated and subject to removal in a future release. For `NDB` tablespaces, the only permitted values for this option are `NDBCLUSTER` and `NDB`.
- For more information about the `CREATE TABLESPACE` and `ALTER TABLESPACE` statements, see Section 13.1.21, “CREATE TABLESPACE Syntax”, and Section 13.1.10, “ALTER TABLESPACE Syntax”.

3. Now it is possible to create a table whose unindexed columns are stored on disk using files in tablespace `ts_1`:

```
CREATE TABLE dt_1 (
    member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    last_name VARCHAR(50) NOT NULL,
    first_name VARCHAR(50) NOT NULL,
    dob DATE NOT NULL,
    joined DATE NOT NULL,
    INDEX(last_name, first_name)
    )
    TABLESPACE ts_1 STORAGE DISK
    ENGINE NDBCLUSTER;
```

`TABLESPACE ts_1 STORAGE DISK` tells the `NDB` storage engine to use tablespace `ts_1` for data storage on disk.

Once table `ts_1` has been created as shown, you can perform `INSERT`, `SELECT`, `UPDATE`, and `DELETE` statements on it just as you would with any other MySQL table.

It is also possible to specify whether an individual column is stored on disk or in memory by using a `STORAGE` clause as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. See Section 13.1.20, “CREATE TABLE Syntax”, for more information.

You can obtain information about the `NDB` disk data files and undo log files just created by querying the `FILES` table in the `INFORMATION_SCHEMA` database, as shown here:

```
mysql> SELECT
             FILE_NAME AS File, FILE_TYPE AS Type,
             TABLESPACE_NAME AS Tablespace, TABLE_NAME AS Name,
             LOGFILE_GROUP_NAME AS 'File group',
             FREE_EXTENTS AS Free, TOTAL_EXTENTS AS Total
          FROM INFORMATION_SCHEMA.FILES
          WHERE ENGINE='ndbcluster';
+--------------+----------+------------+------+------------+------+---------+
| File         | Type     | Tablespace | Name | File group | Free | Total   |
+--------------+----------+------------+------+------------+------+---------+
| ./undo_1.log | UNDO LOG | lg_1       | NULL | lg_1       |    0 | 4194304 |
```

```
| ./undo_2.log | UNDO LOG | lg_1       | NULL | lg_1       |    0 | 3145728 |
| ./data_1.dat | DATAFILE | ts_1       | NULL | lg_1       |   32 |      32 |
| ./data_2.dat | DATAFILE | ts_1       | NULL | lg_1       |   48 |      48 |
+--------------+----------+------------+------+------------+------+---------+
4 rows in set (0.00 sec)
```

For more information and examples, see Section 25.11, “The INFORMATION_SCHEMA FILES Table”.

Indexing of columns implicitly stored on disk. For table `dt_1` as defined in the example just shown, only the `dob` and `joined` columns are stored on disk. This is because there are indexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. Only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

You cannot add an index to a column that has been explicitly declared `STORAGE DISK`, without first changing its storage type to `MEMORY`; any attempt to do so fails with an error. A column which *implicitly* uses disk storage can be indexed; when this is done, the column's storage type is changed to `MEMORY` automatically. By “implicitly”, we mean a column whose storage type is not declared, but which is which inherited from the parent table. In the following CREATE TABLE statement (using the tablespace `ts_1` defined previously), columns `c2` and `c3` use disk storage implicitly:

```
mysql> CREATE TABLE ti (
    ->     c1 INT PRIMARY KEY,
    ->     c2 INT,
    ->     c3 INT,
    ->     c4 INT
    -> )
    ->     STORAGE DISK
    ->     TABLESPACE ts_1
    ->     ENGINE NDBCLUSTER;
Query OK, 0 rows affected (1.31 sec)
```

Because `c2`, `c3`, and `c4` are themselves not declared with `STORAGE DISK`, it is possible to index them. Here, we add indexes to `c2` and `c3`, using, respectively, `CREATE INDEX` and `ALTER TABLE`:

```
mysql> CREATE INDEX i1 ON ti(c2);
Query OK, 0 rows affected (2.72 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> ALTER TABLE ti ADD INDEX i2(c3);
Query OK, 0 rows affected (0.92 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

`SHOW CREATE TABLE` confirms that the indexes were added.

```
mysql> SHOW CREATE TABLE ti\G
*************************** 1. row ***************************
       Table: ti
Create Table: CREATE TABLE `ti` (
  `c1` int(11) NOT NULL,
  `c2` int(11) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
  `c4` int(11) DEFAULT NULL,
  PRIMARY KEY (`c1`),
  KEY `i1` (`c2`),
  KEY `i2` (`c3`)
) /*!50100 TABLESPACE `ts_1` STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

You can see using `ndb_desc` that the indexed columns (emphasized text) now use in-memory rather than on-disk storage:

```
shell> ./ndb_desc -d test t1
-- t1 --
```

```

```

Performance note. The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You can use absolute and relative file system paths with `ADD UNDOFILE` and `ADD DATAFILE`; relative paths are calculated with respect to the data node's data directory. You can also use symbolic links to point to a directory on a different disk; see Section 22.5.13.2, “Using Symbolic Links with Disk Data Objects”, for more information and examples.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. This is also true for dropping these objects, sibject to the following constraints:

- A log file group cannot be dropped as long as any tablespaces use it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- It is not possible to drop files created in association with a different tablespace other than the one with which the files were created.

For example, to drop all the objects created so far in this section, you can use the following statements:

```
mysql> DROP TABLE dt_1;

mysql> ALTER TABLESPACE ts_1
    -> DROP DATAFILE 'data_2.dat'
    -> ENGINE NDBCLUSTER;

mysql> ALTER TABLESPACE ts_1
    -> DROP DATAFILE 'data_1.dat'
    -> ENGINE NDBCLUSTER;
```

```
mysql> DROP TABLESPACE ts_1
    -> ENGINE NDBCLUSTER;

mysql> DROP LOGFILE GROUP lg_1
    -> ENGINE NDBCLUSTER;
```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE ... DROP DATAFILE` statements may be executed in either order.

22.5.13.2 Using Symbolic Links with Disk Data Objects

The performance of an NDB Cluster that uses Disk Data storage can be greatly improved by separating the data node file system from any tablespace files (undo log files and data files), and placing these on different disks. In early versions of NDB Cluster, there was no direct support for this in NDB Cluster, but it was possible to achieve this separation using symbolic links as described in this section. NDB Cluster supports the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`, which make the use of symbolic links for this purpose unnecessary. For more information about these parameters, see Disk Data file system parameters.

Each data node in the cluster creates a file system in the directory named `ndb_node_id_fs` under the data node's `DataDir` as defined in the `config.ini` file. In this example, we assume that each data node host has 3 disks, aliased as `/data0`, `/data1`, and `/data2`, and that the cluster's `config.ini` includes the following:

```
[ndbd default]
DataDir= /data0
```

Our objective is to place all Disk Data log files in `/data1`, and all Disk Data data files in `/data2`, on each data node host.

Note

In this example, we assume that the cluster's data node hosts are all using Linux operating systems. For other platforms, you may need to substitute you operating system's commands for those shown here.

To accomplish this, perform the following steps:

- Under the data node file system create symbolic links pointing to the other drives:

  ```
  shell> cd /data0/ndb_2_fs
  shell> ls
  D1  D10  D11  D2  D8  D9  LCP
  shell> ln -s /data0 dnlogs
  shell> ln -s /data1 dndata
  ```

  You should now have two symbolic links:

  ```
  shell> ls -l --hide=D*
  lrwxrwxrwx 1 user group   30 2007-03-19 13:58 dndata -> /data1
  lrwxrwxrwx 1 user group   30 2007-03-19 13:59 dnlogs -> /data2
  ```

  We show this only for the data node with node ID 2; however, you must do this for *each* data node.

- Now, in the `mysql` client, create a log file group and tablespace using the symbolic links, as shown here:

  ```
  mysql> CREATE LOGFILE GROUP lg1
      ->    ADD UNDOFILE 'dnlogs/undo1.log'
      ->    INITIAL_SIZE 150M
  ```

```
    ->    UNDO_BUFFER_SIZE = 1M
    ->    ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
    ->    ADD DATAFILE 'dndata/data1.log'
    ->    USE LOGFILE GROUP lg1
    ->    INITIAL_SIZE 1G
    ->    ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```
shell> cd /data1
shell> ls -l
total 2099304
-rw-rw-r--  1 user group 157286400 2007-03-19 14:02 undo1.dat

shell> cd /data2
shell> ls -l
total 2099304
-rw-rw-r--  1 user group 1073741824 2007-03-19 14:02 data1.dat
```

- If you are running multiple data nodes on one host, you must take care to avoid having them try to use the same space for Disk Data files. You can make this easier by creating a symbolic link in each data node file system. Suppose you are using `/data0` for both data node file systems, but you wish to have the Disk Data files for both nodes on `/data1`. In this case, you can do something similar to what is shown here:

```
shell> cd /data0
shell> ln -s /data1/dn2 ndb_2_fs/dd
shell> ln -s /data1/dn3 ndb_3_fs/dd
shell> ls -l --hide=D* ndb_2_fs
lrwxrwxrwx 1 user group   30 2007-03-19 14:22 dd -> /data1/dn2
shell> ls -l --hide=D* ndb_3_fs
lrwxrwxrwx 1 user group   30 2007-03-19 14:22 dd -> /data1/dn3
```

- Now you can create a logfile group and tablespace using the symbolic link, like this:

```
mysql> CREATE LOGFILE GROUP lg1
    ->    ADD UNDOFILE 'dd/undo1.log'
    ->    INITIAL_SIZE 150M
    ->    UNDO_BUFFER_SIZE = 1M
    ->    ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
    ->    ADD DATAFILE 'dd/data1.log'
    ->    USE LOGFILE GROUP lg1
    ->    INITIAL_SIZE 1G
    ->    ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```
shell> cd /data1
shell> ls
dn2        dn3
shell> ls dn2
undo1.log        data1.log
shell> ls dn3
undo1.log        data1.log
```

22.5.13.3 NDB Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

For general information about calculating these values, see Section 11.8, “Data Type Storage Requirements”.

You can obtain an estimate the amount of space available in data files and undo log files by querying the `INFORMATION_SCHEMA.FILES` table. For more information and examples, see Section 25.11, “The INFORMATION_SCHEMA FILES Table”.

Note

The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a `TEXT` or `BLOB` column are stored in memory; only the remainder is stored on disk.
- Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a `CHAR(4)` column from memory-based to disk-based format increases the amount of `DataMemory` used per row from 4 to 8 bytes.

Important

Starting the cluster with the `--initial` option does *not* remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that `DiskPageBufferMemory` is of sufficient size. You can query the `diskpagebuffer` table to help determine whether the value for this parameter needs to be increased.

22.5.14 Online Operations with ALTER TABLE in NDB Cluster

MySQL NDB Cluster 8.0 supports online table schema changes using the standard `ALTER TABLE` syntax employed by the MySQL Server (`ALGORITHM=DEFAULT|INPLACE|COPY`), and described elsewhere.

Note

Some older releases of NDB Cluster used a syntax specific to `NDB` for online `ALTER TABLE` operations. That syntax has since been removed.

Operations that add and drop indexes on variable-width columns of `NDB` tables occur online. Online operations are noncopying; that is, they do not require that indexes be re-created. They do not lock the table being altered from access by other API nodes in an NDB Cluster (but see Limitations of NDB online operations, later in this section). Such operations do not require single user mode for `NDB` table alterations made in an NDB cluster with multiple API nodes; transactions can continue uninterrupted during online DDL operations.

`ALGORITHM=INPLACE` can be used to perform online `ADD COLUMN`, `ADD INDEX` (including `CREATE INDEX` statements), and `DROP INDEX` operations on `NDB` tables. Online renaming of `NDB` tables is also supported.

Currently you cannot add disk-based columns to `NDB` tables online. This means that, if you wish to add an in-memory column to an `NDB` table that uses a table-level `STORAGE DISK` option, you must declare the new column as using memory-based storage explicitly. For example—assuming that you have already created tablespace `ts1`—suppose that you create table `t1` as follows:

```
mysql> CREATE TABLE t1 (
    >     c1 INT NOT NULL PRIMARY KEY,
    >     c2 VARCHAR(30)
```

```
    >     )
    >     TABLESPACE ts1 STORAGE DISK
    >     ENGINE NDB;
Query OK, 0 rows affected (1.73 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

You can add a new in-memory column to this table online as shown here:

```
mysql> ALTER TABLE t1
    >     ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC STORAGE MEMORY,
    >     ALGORITHM=INPLACE;
Query OK, 0 rows affected (1.25 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

This statement fails if the `STORAGE MEMORY` option is omitted:

```
mysql> ALTER TABLE t1
    >     ADD COLUMN c4 INT COLUMN_FORMAT DYNAMIC,
    >     ALGORITHM=INPLACE;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason:
Adding column(s) or add/reorganize partition not supported online. Try
ALGORITHM=COPY.
```

If you omit the `COLUMN_FORMAT DYNAMIC` option, the dynamic column format is employed automatically, but a warning is issued, as shown here:

```
mysql> ALTER ONLINE TABLE t1 ADD COLUMN c4 INT STORAGE MEMORY;
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Warning
   Code: 1478
Message: DYNAMIC column c4 with STORAGE DISK is not supported, column will
become FIXED

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (
  `c1` int(11) NOT NULL,
  `c2` varchar(30) DEFAULT NULL,
  `c3` int(11) /*!50606 STORAGE MEMORY */ /*!50606 COLUMN_FORMAT DYNAMIC */ DEFAULT NULL,
  `c4` int(11) /*!50606 STORAGE MEMORY */ DEFAULT NULL,
  PRIMARY KEY (`c1`)
) /*!50606 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.03 sec)
```

Note

The `STORAGE` and `COLUMN_FORMAT` keywords are supported only in NDB Cluster; in any other version of MySQL, attempting to use either of these keywords in a `CREATE TABLE` or `ALTER TABLE` statement results in an error.

It is also possible to use the statement `ALTER TABLE ... REORGANIZE PARTITION, ALGORITHM=INPLACE` with no *`partition_names INTO (partition_definitions)`* option on `NDB` tables. This can be used to redistribute NDB Cluster data among new data nodes that have been added to the cluster online. This does *not* perform any defragmentation, which requires an `OPTIMIZE TABLE` or null `ALTER TABLE` statement. For more information, see Section 22.5.15, “Adding NDB Cluster Data Nodes Online”.

Limitations of NDB online operations

Online `DROP COLUMN` operations are not supported.

Online `ALTER TABLE`, `CREATE INDEX`, or `DROP INDEX` statements that add columns or add or drop indexes are subject to the following limitations:

- A given online `ALTER TABLE` can use only one of `ADD COLUMN`, `ADD INDEX`, or `DROP INDEX`. One or more columns can be added online in a single statement; only one index may be created or dropped online in a single statement.
- The table being altered is not locked with respect to API nodes other than the one on which an online `ALTER TABLE ADD COLUMN`, `ADD INDEX`, or `DROP INDEX` operation (or `CREATE INDEX` or `DROP INDEX` statement) is run. However, the table is locked against any other operations originating on the *same* API node while the online operation is being executed.
- The table to be altered must have an explicit primary key; the hidden primary key created by the `NDB` storage engine is not sufficient for this purpose.
- The storage engine used by the table cannot be changed online.
- When used with NDB Cluster Disk Data tables, it is not possible to change the storage type (`DISK` or `MEMORY`) of a column online. This means, that when you add or drop an index in such a way that the operation would be performed online, and you want the storage type of the column or columns to be changed, you must use `ALGORITHM=COPY` in the statement that adds or drops the index.

Columns to be added online cannot use the `BLOB` or `TEXT` type, and must meet the following criteria:

- The columns must be dynamic; that is, it must be possible to create them using `COLUMN_FORMAT DYNAMIC`. If you omit the `COLUMN_FORMAT DYNAMIC` option, the dynamic column format is employed automatically.
- The columns must permit `NULL` values and not have any explicit default value other than `NULL`. Columns added online are automatically created as `DEFAULT NULL`, as can be seen here:

```
mysql> CREATE TABLE t2 (
     >     c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
     >     ) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2
     >     ADD COLUMN c2 INT,
     >     ADD COLUMN c3 INT,
     >     ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t2` (
  `c1` int(11) NOT NULL AUTO_INCREMENT,
  `c2` int(11) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
  PRIMARY KEY (`c1`)
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

- The columns must be added following any existing columns. If you attempt to add a column online before any existing columns or using the `FIRST` keyword, the statement fails with an error.
- Existing table columns cannot be reordered online.

For online `ALTER TABLE` operations on `NDB` tables, fixed-format columns are converted to dynamic when they are added online, or when indexes are created or dropped online, as shown here (repeating the `CREATE TABLE` and `ALTER TABLE` statements just shown for the sake of clarity):

```
mysql> CREATE TABLE t2 (
     >     c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
```

```
    >     ) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2
    >     ADD COLUMN c2 INT,
    >     ADD COLUMN c3 INT,
    >     ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW WARNINGS;
*************************** 1. row ***************************
  Level: Warning
   Code: 1478
Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN
*************************** 2. row ***************************
  Level: Warning
   Code: 1478
Message: Converted FIXED field 'c3' to DYNAMIC to enable online ADD COLUMN
2 rows in set (0.00 sec)
```

Only the column or columns to be added online must be dynamic. Existing columns need not be; this includes the table's primary key, which may also be `FIXED`, as shown here:

```
mysql> CREATE TABLE t3 (
    >     c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY COLUMN_FORMAT FIXED
    >     ) ENGINE=NDB;
Query OK, 0 rows affected (2.10 sec)

mysql> SHOW WARNINGS;
*************************** 1. row ***************************
  Level: Warning
   Code: 1478
Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN
1 row in set (0.00 sec)
```

Columns are not converted from `FIXED` to `DYNAMIC` column format by renaming operations. For more information about `COLUMN_FORMAT`, see Section 13.1.20, “CREATE TABLE Syntax”.

The `KEY`, `CONSTRAINT`, and `IGNORE` keywords are supported in `ALTER TABLE` statements using `ALGORITHM=INPLACE`.

Setting `MAX_ROWS` to 0 using an online `ALTER TABLE` statement is disallowed. You must use a copying `ALTER TABLE` to perform this operation. (Bug #21960004)

22.5.15 Adding NDB Cluster Data Nodes Online

This section describes how to add NDB Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process.

Important

Currently, you must add new data nodes to an NDB Cluster as part of a new node group. In addition, it is not possible to change the number of replicas (or the number of nodes per node group) online.

22.5.15.1 Adding NDB Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding NDB Cluster nodes online.

Redistribution of Data. The ability to add new nodes online includes a means to reorganize `NDBCLUSTER` table data and indexes so that they are distributed across all data nodes, including

the new ones, by means of the `ALTER TABLE ... REORGANIZE PARTITION` statement. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed).

The redistribution for `NDBCLUSTER` tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in `mysql` or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

Partial starts. It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

Effects on ongoing operations. Normal DML operations using NDB Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an `ALTER TABLE ... REORGANIZE PARTITION` statement is executing. In addition, during the execution of `ALTER TABLE ... REORGANIZE PARTITION` (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

Failure handling. Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

Table 22.411 Data node failure handling during node group creation and table reorganization

Failure during	Failure in “Old” data node	Failure in “New” data node	System Failure

Node group creation	• **If a node other than the master fails:** The creation of the node group is always rolled forward.
	• **If the master fails:**
	  • **If the internal commit point has been reached:** The creation of the node group is rolled forward.
	  • **If the internal commit point has not yet been reached.** The creation of the node group is rolled back
		• **If a node other than the master fails:** The creation of the node group is always rolled forward.
		• **If the master fails:**
		  • **If the internal commit point has been reached:** The creation of the node group is rolled forward.
		  • **If the internal commit point has not yet been reached.** The creation of the node group is rolled back
			• **If the execution of CREATE NODEGROUP has reached the internal commit point:** When restarted, the cluster includes the new node group. Otherwise it without.
			• **If the execution of CREATE NODEGROUP has not yet reached the internal commit point:** When restarted, the cluster does not include the new node group.

Table reorganization	• **If a node other than the master fails:** The table reorganization is always rolled forward. • **If the master fails:**	• **If a node other than the master fails:** The table reorganization is always rolled forward. • **If the master fails:**	• **If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has reached the internal commit point:** When the cluster is restarted, the

Failure during	Failure in “Old” data node	Failure in “New” data node	System Failure
	• **If the internal commit point has been reached:** The table reorganization is rolled forward. • **If the internal commit point has not yet been reached.** The table reorganization is rolled back.	• **If the internal commit point has been reached:** The table reorganization is rolled forward. • **If the internal commit point has not yet been reached.** The table reorganization is rolled back.	data and indexes belonging to *`table`* are distributed using the “new” data nodes. • **If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has not yet reached the internal commit point:** When the cluster is restarted, the data and indexes belonging to *`table`* are distributed using only the “old” data nodes.

Dropping node groups. The `ndb_mgm` client supports a `DROP NODEGROUP` command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

   `TRUNCATE TABLE` does not work for this purpose because the data nodes continue to store the table definitions.

22.5.15.2 Adding NDB Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to an NDB Cluster. This procedure applies whether you are using `ndbd` or `ndbmtd` binaries for the data node processes. For a more detailed example, see Section 22.5.15.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”.

Assuming that you already have a running NDB Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.

   You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to “migrate”, as described later in this procedure.

2. Perform a rolling restart of all NDB Cluster management servers.

Important

All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing NDB Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` when restarting the existing data nodes.

   If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the NDB Cluster.

5. Start the new data nodes.

   The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the NDB Cluster management client to create the new node group or node groups to which the new data nodes will belong.

7. Redistribute the cluster's data among all data nodes, including the new ones. Normally this is done by issuing an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

   Exception: For tables created using the `MAX_ROWS` option, this statement does not work; instead, use `ALTER TABLE ... ALGORITHM=INPLACE MAX_ROWS=...` to reorganize such tables. You should also bear in mind that using `MAX_ROWS` to set the number of partitions in this fashion is deprecated, and you should use `PARTITION_BALANCE` instead; see Section 13.1.20.11, “Setting NDB_TABLE Options”, for more information.

   Note

   This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized.

8. `ALTER TABLE ... REORGANIZE PARTITION ALGORITHM=INPLACE` reorganizes partitions but does not reclaim the space freed on the “old” nodes. You can do this by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

   This works for space used by variable-width columns of in-memory `NDB` tables. `OPTIMIZE TABLE` is not supported for fixed-width columns of in-memory tables; it is also not supported for Disk Data tables.

You can add all the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster.

22.5.15.3 Adding NDB Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new NDB Cluster data nodes online, starting with an NDB Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

Starting configuration. For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster
```

```
[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

Note

We have left a gap in the sequence between data node IDs and other nodes. This make it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @198.51.100.1  (8.0.16-ndb-8.0.16, Nodegroup: 0, *)
id=2    @198.51.100.2  (8.0.16-ndb-8.0.16, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @198.51.100.10  (8.0.16-ndb-8.0.16)

[mysqld(API)]   2 node(s)
id=20   @198.51.100.20  (8.0.16-ndb-8.0.16)
id=21   @198.51.100.21  (8.0.16-ndb-8.0.16)
```

Finally, we assume that the cluster contains a single `NDBCLUSTER` table created as shown here:

```
USE n;

CREATE TABLE ips (
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    country_code CHAR(2) NOT NULL,
    type CHAR(4) NOT NULL,
    ip_address VARCHAR(15) NOT NULL,
    addresses BIGINT UNSIGNED DEFAULT NULL,
    date BIGINT UNSIGNED DEFAULT NULL
)   ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

Note

In this example, we show the single-threaded `ndbd` being used for the data node processes. You can also apply this example, if you are using the

multithreaded `ndbmtd` by substituting `ndbmtd` for `ndbd` wherever it appears in the steps that follow.

Step 1: Update configuration file. Open the cluster global configuration file in a text editor and add `[ndbd]` sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 198.51.100.3 and 198.51.100.4, respectively.) After you have added the new sections, the contents of the `config.ini` file should look like what is shown here, where the additions to the file are shown in bold type:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[ndbd]
Id = 3
HostName = 198.51.100.3

[ndbd]
Id = 4
HostName = 198.51.100.4

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

Once you have made the necessary changes, save the file.

Step 2: Restart the management server. Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client `STOP` command, as shown here:

   ```
   ndb_mgm> 10 STOP
   Node 10 has shut down.
   Disconnecting to allow Management Server to shutdown

   shell>
   ```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

   ```
   shell> ndb_mgmd -f config.ini --reload
   ```

```
2008-12-08 17:29:23 [MgmSrvr] INFO     -- NDB Cluster Management Server. 8.0.16-ndb-8.0.16
2008-12-08 17:29:23 [MgmSrvr] INFO     -- Reading cluster configuration from 'config.ini'
```

If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @198.51.100.1  (8.0.16-ndb-8.0.16, Nodegroup: 0, *)
id=2    @198.51.100.2  (8.0.16-ndb-8.0.16, Nodegroup: 0)
id=3 (not connected, accepting connect from 198.51.100.3)
id=4 (not connected, accepting connect from 198.51.100.4)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @198.51.100.10  (8.0.16-ndb-8.0.16)

[mysqld(API)]   2 node(s)
id=20   @198.51.100.20  (8.0.16-ndb-8.0.16)
id=21   @198.51.100.21  (8.0.16-ndb-8.0.16)
```

Step 3: Perform a rolling restart of the existing data nodes. This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 8.0.16)
Node 1: Started (version 8.0.16)

ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted

ndb_mgm> Node 2: Start initiated (version 8.0.16)

ndb_mgm> Node 2: Started (version 8.0.16)
```

Important

After issuing each *`X`* `RESTART` command, wait until the management client reports `Node` *`X`*`: Started (version ...)` *before* proceeding any further.

You can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

Step 4: Perform a rolling restart of all cluster API nodes. Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where *`password`* is the MySQL `root` password for a given MySQL server instance:

```
shell> mysqladmin -uroot -ppassword shutdown
081208 20:19:56 mysqld_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
shell> mysqld_safe --ndbcluster --ndb-connectstring=198.51.100.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

Step 5: Perform an initial start of the new data nodes. From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```
shell> ndbd -c 198.51.100.10 --initial
```

Note

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

Wait until both of the new data nodes have started before proceeding with the next step. Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @198.51.100.1  (8.0.16-ndb-8.0.16, Nodegroup: 0, *)
id=2    @198.51.100.2  (8.0.16-ndb-8.0.16, Nodegroup: 0)
id=3    @198.51.100.3  (8.0.16-ndb-8.0.16, no nodegroup)
id=4    @198.51.100.4  (8.0.16-ndb-8.0.16, no nodegroup)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @198.51.100.10  (8.0.16-ndb-8.0.16)

[mysqld(API)]   2 node(s)
id=20   @198.51.100.20  (8.0.16-ndb-8.0.16)
id=21   @198.51.100.21  (8.0.16-ndb-8.0.16)
```

Step 6: Create a new node group. You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @198.51.100.1  (8.0.16-ndb-8.0.16, Nodegroup: 0, *)
id=2    @198.51.100.2  (8.0.16-ndb-8.0.16, Nodegroup: 0)
id=3    @198.51.100.3  (8.0.16-ndb-8.0.16, Nodegroup: 1)
id=4    @198.51.100.4  (8.0.16-ndb-8.0.16, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @198.51.100.10  (8.0.16-ndb-8.0.16)

[mysqld(API)]   2 node(s)
id=20   @198.51.100.20  (8.0.16-ndb-8.0.16)
id=21   @198.51.100.21  (8.0.16-ndb-8.0.16)
```

Step 7: Redistribute cluster data. When a node group is created, existing data and indexes are not automatically distributed to the new node group's data nodes, as you can see by issuing the appropriate `REPORT` command in the management client:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the `Per partition info` section of the output, shown here in bold text):

```
shell> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --
Version: 1
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 340
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY

PRIMARY(id) - OrderedIndex

-- Per partition info --
Partition   Row count   Commit count  Frag fixed memory   Frag varsized memory
0           26086       26086         1572864             557056
1           26329       26329         1605632             557056

NDBT_ProgramExit: 0 - OK
```

You can cause the data to be redistributed among all of the data nodes by performing, for each `NDB` table, an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client.

Important

`ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` does not work on tables that were created with the `MAX_ROWS` option. Instead, use `ALTER TABLE ... ALGORITHM=INPLACE, MAX_ROWS=...` to reorganize such tables.

Keep in mind that using `MAX_ROWS` to set the number of partitions per table is deprecated, and you should use `PARTITION_BALANCE` instead; see Section 13.1.20.11, “Setting NDB_TABLE Options”, for more information.

After issuing the statement `ALTER TABLE ips ALGORITHM=INPLACE, REORGANIZE PARTITION`, you can see using `ndb_desc` that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```
shell> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --

NDBT_ProgramExit: 0 - OK
```

Note

Normally, `ALTER TABLE table_name [ALGORITHM=INPLACE,] REORGANIZE PARTITION` is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new NDB Cluster node group is an exception in this regard; when used in this way, no other keywords or identifiers follow `REORGANIZE PARTITION`.

For more information, see Section 13.1.9, “ALTER TABLE Syntax”.

In addition, for each table, the `ALTER TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all `NDBCLUSTER` tables using the following query against the `INFORMATION_SCHEMA.TABLES` table:

```
SELECT TABLE_SCHEMA, TABLE_NAME
    FROM INFORMATION_SCHEMA.TABLES
    WHERE ENGINE = 'NDBCLUSTER';
```

Note

The `INFORMATION_SCHEMA.TABLES.ENGINE` value for an NDB Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)
```

Note

Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created *after* the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed *prior to* the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER TABLE ... REORGANIZE PARTITION`.

Alternative procedure, without rolling restart. It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[ndbd]
Id = 3
HostName = 198.51.100.3
Nodegroup = 65536

[ndbd]
Id = 4
HostName = 198.51.100.4
Nodegroup = 65536

[mgm]
HostName = 198.51.100.10
```

```
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

The data nodes to be brought online at a later time (nodes 3 and 4) can be configured with `NodeGroup = 65536`, in which case nodes 1 and 2 can each be started as shown here:

```
shell> ndbd -c 198.51.100.10 --initial
```

The data nodes configured with `NodeGroup = 65536` are treated by the management server as though you had started nodes 1 and 2 using `--nowait-nodes=3,4` after waiting for a period of time determined by the setting for the `StartNoNodeGroupTimeout` data node configuration parameter. By default, this is 15 seconds (15000 milliseconds).

Note

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

   ```
   shell> ndbd -c 198.51.100.10 --initial
   ```

2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

   ```
   ndb_mgm> CREATE NODEGROUP 3,4
   ```

3. In the `mysql` client, issue `ALTER TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing NDB Cluster tables cannot use the new nodes for data distribution until this has been done.)

22.5.16 Distributed MySQL Privileges for NDB Cluster

NDB Cluster supports distribution of MySQL users and privileges across all SQL nodes in an NDB Cluster. This support is not enabled by default; you should follow the procedure outlined in this section in order to do so.

Normally, each MySQL server's user privilege tables in the `mysql` database must use the `MyISAM` storage engine, which means that a user account and its associated privileges created on one SQL node are not available on the cluster's other SQL nodes. An SQL file `ndb_dist_priv.sql` provided with the NDB Cluster distribution can be found in the `share` directory in the MySQL installation directory.

The first step in enabling distributed privileges is to load this script into a MySQL Server that functions as an SQL node (which we refer to after this as the *target* SQL node or MySQL Server). You can do this by executing the following command from the system shell on the target SQL node after changing to its MySQL installation directory (where *`options`* stands for any additional options needed to connect to this SQL node):

```
shell> mysql options -uroot < share/ndb_dist_priv.sql
```

Importing `ndb_dist_priv.sql` creates a number of stored routines (six stored procedures and one stored function) in the `mysql` database on the target SQL node. After connecting to the SQL node in the `mysql` client (as the MySQL `root` user), you can verify that these were created as shown here:

```
mysql> SELECT ROUTINE_NAME, ROUTINE_SCHEMA, ROUTINE_TYPE
    ->     FROM INFORMATION_SCHEMA.ROUTINES
    ->     WHERE ROUTINE_NAME LIKE 'mysql_cluster%'
    ->     ORDER BY ROUTINE_TYPE;
+-----------------------------------------+----------------+--------------+
| ROUTINE_NAME                            | ROUTINE_SCHEMA | ROUTINE_TYPE |
+-----------------------------------------+----------------+--------------+
| mysql_cluster_privileges_are_distributed | mysql          | FUNCTION     |
| mysql_cluster_backup_privileges         | mysql          | PROCEDURE    |
| mysql_cluster_move_grant_tables         | mysql          | PROCEDURE    |
| mysql_cluster_move_privileges           | mysql          | PROCEDURE    |
| mysql_cluster_restore_local_privileges  | mysql          | PROCEDURE    |
| mysql_cluster_restore_privileges        | mysql          | PROCEDURE    |
| mysql_cluster_restore_privileges_from_local | mysql          | PROCEDURE    |
+-----------------------------------------+----------------+--------------+
7 rows in set (0.01 sec)
```

The stored procedure named `mysql_cluster_move_privileges` creates backup copies of the existing privilege tables, then converts them to `NDB`.

`mysql_cluster_move_privileges` performs the backup and conversion in two steps. The first step is to call `mysql_cluster_backup_privileges`, which creates two sets of copies in the `mysql` database:

- A set of local copies that use the `MyISAM` storage engine. Their names are generated by adding the suffix `_backup` to the original privilege table names.
- A set of distributed copies that use the `NDBCLUSTER` storage engine. These tables are named by prefixing `ndb_` and appending `_backup` to the names of the original tables.

After the copies are created, `mysql_cluster_move_privileges` invokes `mysql_cluster_move_grant_tables`, which contains the `ALTER TABLE ... ENGINE = NDB` statements that convert the mysql system tables to `NDB`.

Normally, you should not invoke either `mysql_cluster_backup_privileges` or `mysql_cluster_move_grant_tables` manually; these stored procedures are intended only for use by `mysql_cluster_move_privileges`.

Although the original privilege tables are backed up automatically, it is always a good idea to create backups manually of the existing privilege tables on all affected SQL nodes before proceeding. You can do this using `mysqldump` in a manner similar to what is shown here:

```
shell> mysqldump options -uroot \
    mysql user db tables_priv columns_priv procs_priv proxies_priv > backup_file
```

To perform the conversion, you must be connected to the target SQL node using the `mysql` client (again, as the MySQL `root` user). Invoke the stored procedure like this:

```
mysql> CALL mysql.mysql_cluster_move_privileges();
Query OK, 0 rows affected (22.32 sec)
```

Depending on the number of rows in the privilege tables, this procedure may take some time to execute. If some of the privilege tables are empty, you may see one or more `No data - zero rows fetched, selected, or processed` warnings when `mysql_cluster_move_privileges` returns. In such cases, the warnings may be safely ignored. To verify that the conversion was successful, you can use the stored function `mysql_cluster_privileges_are_distributed` as shown here:

```
mysql> SELECT CONCAT(
    ->    'Conversion ',
    ->    IF(mysql.mysql_cluster_privileges_are_distributed(), 'succeeded', 'failed'),
    ->    '.')
    ->    AS Result;
+----------------------+
| Result               |
+----------------------+
| Conversion succeeded. |
+----------------------+
1 row in set (0.00 sec)
```

`mysql_cluster_privileges_are_distributed` checks for the existence of the distributed privilege tables and returns `1` if all of the privilege tables are distributed; otherwise, it returns `0`.

You can verify that the backups have been created using a query such as this one:

```
mysql> SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES
    ->     WHERE TABLE_SCHEMA = 'mysql' AND TABLE_NAME LIKE '%backup'
    ->     ORDER BY ENGINE;
+-------------------------+------------+
| TABLE_NAME              | ENGINE     |
+-------------------------+------------+
| db_backup               | MyISAM     |
| user_backup             | MyISAM     |
| columns_priv_backup     | MyISAM     |
| tables_priv_backup      | MyISAM     |
| proxies_priv_backup     | MyISAM     |
| procs_priv_backup       | MyISAM     |
| ndb_columns_priv_backup | ndbcluster |
| ndb_user_backup         | ndbcluster |
| ndb_tables_priv_backup  | ndbcluster |
| ndb_proxies_priv_backup | ndbcluster |
| ndb_procs_priv_backup   | ndbcluster |
| ndb_db_backup           | ndbcluster |
+-------------------------+------------+
12 rows in set (0.00 sec)
```

Once the conversion to distributed privileges has been made, any time a MySQL user account is created, dropped, or has its privileges updated on any SQL node, the changes take effect immediately on all other MySQL servers attached to the cluster. Once privileges are distributed, any new MySQL Servers that connect to the cluster automatically participate in the distribution.

Note

For clients connected to SQL nodes at the time that `mysql_cluster_move_privileges` is executed, you may need to execute `FLUSH PRIVILEGES` on those SQL nodes, or to disconnect and then reconnect the clients, in order for those clients to be able to see the changes in privileges.

All MySQL user privileges are distributed across all connected MySQL Servers. This includes any privileges associated with views and stored routines, even though distribution of views and stored routines themselves is not currently supported.

In the event that an SQL node becomes disconnected from the cluster while `mysql_cluster_move_privileges` is running, you must drop its privilege tables after reconnecting to the cluster, using a statement such as `DROP TABLE IF EXISTS mysql.user mysql.db mysql.tables_priv mysql.columns_priv mysql.procs_priv`. This causes the SQL node to use the shared privilege tables rather than its own local versions of them. This is not needed when connecting a new SQL node to the cluster for the first time.

In the event of an initial restart of the entire cluster (all data nodes shut down, then started again with `--initial`), the shared privilege tables are lost. If this happens, you can restore them using the original target SQL node either from the backups made by `mysql_cluster_move_privileges` or from a dump file created with `mysqldump`. If you need to use a new MySQL Server to perform

the restoration, you should start it with `--skip-grant-tables` when connecting to the cluster for the first time; after this, you can restore the privilege tables locally, then distribute them again using `mysql_cluster_move_privileges`. After restoring and distributing the tables, you should restart this MySQL Server without the `--skip-grant-tables` option.

You can also restore the distributed tables using `ndb_restore --restore-privilege-tables` from a backup made using `START BACKUP` in the `ndb_mgm` client. (The `MyISAM` tables created by `mysql_cluster_move_privileges` are not backed up by the `START BACKUP` command.) `ndb_restore` does not restore the privilege tables by default; the `--restore-privilege-tables` option causes it to do so.

You can restore the SQL node's local privileges using either of two procedures. `mysql_cluster_restore_privileges` works as follows:

1. If copies of the `mysql.ndb_*_backup` tables are available, attempt to restore the system tables from these.
2. Otherwise, attempt to restore the system tables from the local backups named `*_backup` (without the `ndb_` prefix).

The other procedure, named `mysql_cluster_restore_local_privileges`, restores the system tables from the local backups only, without checking the `ndb_*` backups.

The system tables re-created by `mysql_cluster_restore_privileges` or `mysql_cluster_restore_local_privileges` use the MySQL server default storage engine; they are not shared or distributed in any way, and do not use NDB Cluster's `NDB` storage engine.

The additional stored procedure `mysql_cluster_restore_privileges_from_local` is intended for the use of `mysql_cluster_restore_privileges` and `mysql_cluster_restore_local_privileges`. It should not be invoked directly.

Important

Applications that access NDB Cluster data directly, including NDB API and ClusterJ applications, are not subject to the MySQL privilege system. This means that, once you have distributed the grant tables, they can be freely accessed by such applications, just as they can any other `NDB` tables. In particular, you should keep in mind that *NDB API and ClusterJ applications can read and write user names, host names, password hashes, and any other contents of the distributed grant tables without any restrictions*.

22.5.17 NDB API Statistics Counters and Variables

A number of types of statistical counters relating to actions performed by or affecting `Ndb` objects are available. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion of various operations; and data and events sent and received by `NDBCLUSTER`. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. `mysqld` exposes these counters as system status variables; their values can be read in the output of `SHOW STATUS`, or by querying the `INFORMATION_SCHEMA.SESSION_STATUS` or `INFORMATION_SCHEMA.GLOBAL_STATUS` table. By comparing the values before and after statements operating on `NDB` tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following `SHOW STATUS` statement:

```
mysql> SHOW STATUS LIKE 'ndb_api%';
+-----------------------------------------------+----------+
| Variable_name                                 | Value    |
+-----------------------------------------------+----------+
| Ndb_api_wait_exec_complete_count_session      | 0        |
```

```
| Ndb_api_wait_scan_result_count_session     | 0        |
| Ndb_api_wait_meta_request_count_session    | 0        |
| Ndb_api_wait_nanos_count_session           | 0        |
| Ndb_api_bytes_sent_count_session           | 0        |
| Ndb_api_bytes_received_count_session       | 0        |
| Ndb_api_trans_start_count_session          | 0        |
| Ndb_api_trans_commit_count_session         | 0        |
| Ndb_api_trans_abort_count_session          | 0        |
| Ndb_api_trans_close_count_session          | 0        |
| Ndb_api_pk_op_count_session                | 0        |
| Ndb_api_uk_op_count_session                | 0        |
| Ndb_api_table_scan_count_session           | 0        |
| Ndb_api_range_scan_count_session           | 0        |
| Ndb_api_pruned_scan_count_session          | 0        |
| Ndb_api_scan_batch_count_session           | 0        |
| Ndb_api_read_row_count_session             | 0        |
| Ndb_api_trans_local_read_row_count_session | 0        |
| Ndb_api_event_data_count_injector          | 0        |
| Ndb_api_event_nondata_count_injector       | 0        |
| Ndb_api_event_bytes_count_injector         | 0        |
| Ndb_api_wait_exec_complete_count_slave     | 0        |
| Ndb_api_wait_scan_result_count_slave       | 0        |
| Ndb_api_wait_meta_request_count_slave      | 0        |
| Ndb_api_wait_nanos_count_slave             | 0        |
| Ndb_api_bytes_sent_count_slave             | 0        |
| Ndb_api_bytes_received_count_slave         | 0        |
| Ndb_api_trans_start_count_slave            | 0        |
| Ndb_api_trans_commit_count_slave           | 0        |
| Ndb_api_trans_abort_count_slave            | 0        |
| Ndb_api_trans_close_count_slave            | 0        |
| Ndb_api_pk_op_count_slave                  | 0        |
| Ndb_api_uk_op_count_slave                  | 0        |
| Ndb_api_table_scan_count_slave             | 0        |
| Ndb_api_range_scan_count_slave             | 0        |
| Ndb_api_pruned_scan_count_slave            | 0        |
| Ndb_api_scan_batch_count_slave             | 0        |
| Ndb_api_read_row_count_slave               | 0        |
| Ndb_api_trans_local_read_row_count_slave   | 0        |
| Ndb_api_wait_exec_complete_count           | 2        |
| Ndb_api_wait_scan_result_count             | 3        |
| Ndb_api_wait_meta_request_count            | 27       |
| Ndb_api_wait_nanos_count                   | 45612023 |
| Ndb_api_bytes_sent_count                   | 992      |
| Ndb_api_bytes_received_count               | 9640     |
| Ndb_api_trans_start_count                  | 2        |
| Ndb_api_trans_commit_count                 | 1        |
| Ndb_api_trans_abort_count                  | 0        |
| Ndb_api_trans_close_count                  | 2        |
| Ndb_api_pk_op_count                        | 1        |
| Ndb_api_uk_op_count                        | 0        |
| Ndb_api_table_scan_count                   | 1        |
| Ndb_api_range_scan_count                   | 0        |
| Ndb_api_pruned_scan_count                  | 0        |
| Ndb_api_scan_batch_count                   | 0        |
| Ndb_api_read_row_count                     | 1        |
| Ndb_api_trans_local_read_row_count         | 1        |
| Ndb_api_event_data_count                   | 0        |
| Ndb_api_event_nondata_count                | 0        |
| Ndb_api_event_bytes_count                  | 0        |
+--------------------------------------------+----------+
60 rows in set (0.02 sec)
```

These status variables are also available from the `SESSION_STATUS` and `GLOBAL_STATUS` tables of the `INFORMATION_SCHEMA` database, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS
    ->   WHERE VARIABLE_NAME LIKE 'ndb_api%';
+--------------------------------------------+----------------+
| VARIABLE_NAME                              | VARIABLE_VALUE |
+--------------------------------------------+----------------+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT_SESSION   | 2              |
```

```
| NDB_API_WAIT_SCAN_RESULT_COUNT_SESSION      | 0              |
| NDB_API_WAIT_META_REQUEST_COUNT_SESSION     | 1              |
| NDB_API_WAIT_NANOS_COUNT_SESSION            | 8144375        |
| NDB_API_BYTES_SENT_COUNT_SESSION            | 68             |
| NDB_API_BYTES_RECEIVED_COUNT_SESSION        | 84             |
| NDB_API_TRANS_START_COUNT_SESSION           | 1              |
| NDB_API_TRANS_COMMIT_COUNT_SESSION          | 1              |
| NDB_API_TRANS_ABORT_COUNT_SESSION           | 0              |
| NDB_API_TRANS_CLOSE_COUNT_SESSION           | 1              |
| NDB_API_PK_OP_COUNT_SESSION                 | 1              |
| NDB_API_UK_OP_COUNT_SESSION                 | 0              |
| NDB_API_TABLE_SCAN_COUNT_SESSION            | 0              |
| NDB_API_RANGE_SCAN_COUNT_SESSION            | 0              |
| NDB_API_PRUNED_SCAN_COUNT_SESSION           | 0              |
| NDB_API_SCAN_BATCH_COUNT_SESSION            | 0              |
| NDB_API_READ_ROW_COUNT_SESSION              | 1              |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT_SESSION  | 1              |
| NDB_API_EVENT_DATA_COUNT_INJECTOR           | 0              |
| NDB_API_EVENT_NONDATA_COUNT_INJECTOR        | 0              |
| NDB_API_EVENT_BYTES_COUNT_INJECTOR          | 0              |
| NDB_API_WAIT_EXEC_COMPLETE_COUNT_SLAVE      | 0              |
| NDB_API_WAIT_SCAN_RESULT_COUNT_SLAVE        | 0              |
| NDB_API_WAIT_META_REQUEST_COUNT_SLAVE       | 0              |
| NDB_API_WAIT_NANOS_COUNT_SLAVE              | 0              |

```

Each `Ndb` object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multithreaded clients which use more than one `Ndb` object concurrently, it is also possible to obtain a summed view of counters from all `Ndb` objects belonging to a given `Ndb_cluster_connection`.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. *This is in spite of the fact that their values can be obtained as either session or global status variables in the `mysql` client*. This means that specifying the `SESSION` or `GLOBAL` keyword with `SHOW STATUS` has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the `SESSION_STATUS` or the `GLOBAL_STATUS` table.

- *Session counters (session specific)*

  Session counters relate to the `Ndb` objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

  In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as "`_session` variables", with a leading underscore.

- *Slave counters (global)*

  This set of counters relates to the `Ndb` objects used by the replication slave SQL thread, if any. If this `mysqld` does not act as a replication slave, or does not use `NDB` tables, then all of these counts are 0.

  We refer to the related status variables as "`_slave` variables" (with a leading underscore).

- *Injector counters (global)*

  Injector counters relate to the `Ndb` object used to listen to cluster events by the binary log injector thread. Even when not writing a binary log, `mysqld` processes attached to an NDB Cluster continue to listen for some events, such as schema changes.

  We refer to the status variables that correspond to NDB API injector counters as "`_injector` variables" (with a leading underscore).

- *Server (Global) counters (global)*

  This set of counters relates to all `Ndb` objects currently used by this `mysqld`. This includes all MySQL client applications, the slave SQL thread (if any), the binlog injector, and the `NDB` utility thread.

  We refer to the status variables that correspond to these counters as "global variables" or "`mysqld`-level variables".

You can obtain values for a particular set of variables by additionally filtering for the substring `session`, `slave`, or `injector` in the variable name (along with the common prefix `Ndb_api`). For `_session` variables, this can be done as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%session';
+-----------------------------------------+---------+
| Variable_name                           | Value   |
+-----------------------------------------+---------+
| Ndb_api_wait_exec_complete_count_session   | 2       |
| Ndb_api_wait_scan_result_count_session     | 0       |
| Ndb_api_wait_meta_request_count_session    | 1       |
| Ndb_api_wait_nanos_count_session           | 8144375 |
| Ndb_api_bytes_sent_count_session           | 68      |
| Ndb_api_bytes_received_count_session       | 84      |
| Ndb_api_trans_start_count_session          | 1       |
| Ndb_api_trans_commit_count_session         | 1       |
| Ndb_api_trans_abort_count_session          | 0       |
| Ndb_api_trans_close_count_session          | 1       |
| Ndb_api_pk_op_count_session                | 1       |
| Ndb_api_uk_op_count_session                | 0       |
| Ndb_api_table_scan_count_session           | 0       |
| Ndb_api_range_scan_count_session           | 0       |
| Ndb_api_pruned_scan_count_session          | 0       |
| Ndb_api_scan_batch_count_session           | 0       |
| Ndb_api_read_row_count_session             | 1       |
| Ndb_api_trans_local_read_row_count_session | 1       |
+-----------------------------------------+---------+
18 rows in set (0.50 sec)
```

To obtain a listing of the NDB API `mysqld`-level status variables, filter for variable names beginning with `ndb_api` and ending in `_count`, like this:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS
    ->     WHERE VARIABLE_NAME LIKE 'ndb_api%count';
+-----------------------------------+----------------+
| VARIABLE_NAME                     | VARIABLE_VALUE |
+-----------------------------------+----------------+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT  | 4              |
| NDB_API_WAIT_SCAN_RESULT_COUNT    | 3              |
| NDB_API_WAIT_META_REQUEST_COUNT   | 28             |
| NDB_API_WAIT_NANOS_COUNT          | 53756398       |
| NDB_API_BYTES_SENT_COUNT          | 1060           |
| NDB_API_BYTES_RECEIVED_COUNT      | 9724           |
| NDB_API_TRANS_START_COUNT         | 3              |
| NDB_API_TRANS_COMMIT_COUNT        | 2              |
| NDB_API_TRANS_ABORT_COUNT         | 0              |
| NDB_API_TRANS_CLOSE_COUNT         | 3              |
| NDB_API_PK_OP_COUNT               | 2              |
| NDB_API_UK_OP_COUNT               | 0              |
| NDB_API_TABLE_SCAN_COUNT          | 1              |
| NDB_API_RANGE_SCAN_COUNT          | 0              |
| NDB_API_PRUNED_SCAN_COUNT         | 0              |
| NDB_API_SCAN_BATCH_COUNT          | 0              |
| NDB_API_READ_ROW_COUNT            | 2              |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT | 2              |
| NDB_API_EVENT_DATA_COUNT          | 0              |
| NDB_API_EVENT_NONDATA_COUNT       | 0              |
| NDB_API_EVENT_BYTES_COUNT         | 0              |
+-----------------------------------+----------------+
21 rows in set (0.09 sec)
```

Not all counters are reflected in all 4 sets of status variables. For the event counters `DataEventsRecvdCount`, `NondataEventsRecvdCount`, and `EventBytesRecvdCount`, only `_injector` and `mysqld`-level NDB API status variables are available:

```
mysql> SHOW STATUS LIKE 'ndb_api%event%';
+---------------------------------------+-------+
| Variable_name                         | Value |
+---------------------------------------+-------+
| Ndb_api_event_data_count_injector     | 0     |
| Ndb_api_event_nondata_count_injector  | 0     |
| Ndb_api_event_bytes_count_injector    | 0     |
| Ndb_api_event_data_count              | 0     |
| Ndb_api_event_nondata_count           | 0     |
| Ndb_api_event_bytes_count             | 0     |
+---------------------------------------+-------+
6 rows in set (0.00 sec)
```

`_injector` status variables are not implemented for any other NDB API counters, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%injector%';
+---------------------------------------+-------+
| Variable_name                         | Value |
+---------------------------------------+-------+
| Ndb_api_event_data_count_injector     | 0     |
| Ndb_api_event_nondata_count_injector  | 0     |
| Ndb_api_event_bytes_count_injector    | 0     |
+---------------------------------------+-------+
3 rows in set (0.00 sec)
```

The names of the status variables can easily be associated with the names of the corresponding counters. Each NDB API statistics counter is listed in the following table with a description as well as the names of any MySQL server status variables corresponding to this counter.

Table 22.412 NDB API statistics counters

Counter Name	Description	Status Variables (by statistic type): • **Session** • **Slave** • **Injector** • **Server**
WaitExecCompleteCount	Number of times thread has been blocked while waiting for execution of an operation to complete. Includes all execute() calls as well as implicit executes for blob operations and auto-increment not visible to clients.	• Ndb_api_wait_exec_complete_coun • Ndb_api_wait_exec_complete_coun • [none] • Ndb_api_wait_exec_complete_coun
WaitScanResultCount	Number of times thread has been blocked while waiting for a scan-based signal, such waiting for additional results, or for a scan to close.	• Ndb_api_wait_scan_result_count_ • Ndb_api_wait_scan_result_count_ • [none] • Ndb_api_wait_scan_result_count
WaitMetaRequestCount	Number of times thread has been blocked waiting for a metadata-based signal; this can occur when waiting for a DDL operation or for an epoch to be started (or ended).	• Ndb_api_wait_meta_request_count • Ndb_api_wait_meta_request_count • [none] • Ndb_api_wait_meta_request_count
WaitNanosCount	Total time (in nanoseconds) spent waiting for some type of signal from the data nodes.	• Ndb_api_wait_nanos_count_sessio • Ndb_api_wait_nanos_count_slave • [none] • Ndb_api_wait_nanos_count
BytesSentCount	Amount of data (in bytes) sent to the data nodes	• Ndb_api_bytes_sent_count_sessio • Ndb_api_bytes_sent_count_slave • [none] • Ndb_api_bytes_sent_count
BytesRecvdCount	Amount of data (in bytes) received from the data nodes	• Ndb_api_bytes_received_count_se • Ndb_api_bytes_received_count_sl • [none] • Ndb_api_bytes_received_count
TransStartCount	Number of transactions started.	• Ndb_api_trans_start_count_sessi • Ndb_api_trans_start_count_slave • [none]

Counter Name	Description	Status Variables (by statistic type): • **Session** • **Slave** • **Injector** • **Server**
		• Ndb_api_trans_start_count
TransCommitCount	Number of transactions committed.	• Ndb_api_trans_commit_count_s • Ndb_api_trans_commit_count_s • [none] • Ndb_api_trans_commit_count
TransAbortCount	Number of transactions aborted.	• Ndb_api_trans_abort_count_se • Ndb_api_trans_abort_count_sl • [none] • Ndb_api_trans_abort_count
TransCloseCount	Number of transactions aborted. (This value may be greater than the sum of TransCommitCount and TransAbortCount.)	• Ndb_api_trans_close_count_se • Ndb_api_trans_close_count_sl • [none] • Ndb_api_trans_close_count
PkOpCount	Number of operations based on or using primary keys. This count includes blob-part table operations, implicit unlocking operations, and auto-increment operations, as well as primary key operations normally visible to MySQL clients.	• Ndb_api_pk_op_count_session • Ndb_api_pk_op_count_slave • [none] • Ndb_api_pk_op_count
UkOpCount	Number of operations based on or using unique keys.	• Ndb_api_uk_op_count_session • Ndb_api_uk_op_count_slave • [none] • Ndb_api_uk_op_count
TableScanCount	Number of table scans that have been started. This includes scans of internal tables.	• Ndb_api_table_scan_count_ses • Ndb_api_table_scan_count_sla • [none] • Ndb_api_table_scan_count
RangeScanCount	Number of range scans that have been started.	• Ndb_api_range_scan_count_ses • Ndb_api_range_scan_count_sla • [none]

Counter Name	Description	Status Variables (by statistic type): • **Session** • **Slave** • **Injector** • **Server**
		• Ndb_api_range_scan_count
PrunedScanCount	Number of scans that have been pruned to a single partition.	• Ndb_api_pruned_scan_count_sessi • Ndb_api_pruned_scan_count_slave • [none] • Ndb_api_pruned_scan_count
ScanBatchCount	Number of batches of rows received. (A *batch* in this context is a set of scan results from a single fragment.)	• Ndb_api_scan_batch_count_sessio • Ndb_api_scan_batch_count_slave • [none] • Ndb_api_scan_batch_count
ReadRowCount	Total number of rows that have been read. Includes rows read using primary key, unique key, and scan operations.	• Ndb_api_read_row_count_session • Ndb_api_read_row_count_slave • [none] • Ndb_api_read_row_count
TransLocalReadRowCount	Number of rows read from the data same node on which the transaction was being run.	• Ndb_api_trans_local_read_row_co • Ndb_api_trans_local_read_row_co • [none] • Ndb_api_trans_local_read_row_co
DataEventsRecvdCount	Number of row change events received.	• [none] • [none] • Ndb_api_event_data_count_injec • Ndb_api_event_data_count
NondataEventsRecvdCount	Number of events received, other than row change events.	• [none] • [none] • Ndb_api_event_nondata_count_inj • Ndb_api_event_nondata_count
EventBytesRecvdCount	Number of bytes of events received.	• [none] • [none] • Ndb_api_event_bytes_count_injec • Ndb_api_event_bytes_count

To see all counts of committed transactions—that is, all `TransCommitCount` counter status variables—you can filter the results of `SHOW STATUS` for the substring `trans_commit_count`, like this:

```
mysql> SHOW STATUS LIKE '%trans_commit_count%';
+-----------------------------------+-------+
| Variable_name                     | Value |
+-----------------------------------+-------+
| Ndb_api_trans_commit_count_session | 1     |
| Ndb_api_trans_commit_count_slave   | 0     |
| Ndb_api_trans_commit_count         | 2     |
+-----------------------------------+-------+
3 rows in set (0.00 sec)
```

From this you can determine that 1 transaction has been committed in the current `mysql` client session, and 2 transactions have been committed on this `mysqld` since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding `_session` status variables immediately before and after performing the statement. In this example, after getting the initial values from `SHOW STATUS`, we create in the `test` database an `NDB` table, named `t`, that has a single column:

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----------------------------------------+--------+
| Variable_name                           | Value  |
+-----------------------------------------+--------+
| Ndb_api_wait_exec_complete_count_session   | 2      |
| Ndb_api_wait_scan_result_count_session     | 0      |
| Ndb_api_wait_meta_request_count_session    | 3      |
| Ndb_api_wait_nanos_count_session           | 820705 |
| Ndb_api_bytes_sent_count_session           | 132    |
| Ndb_api_bytes_received_count_session       | 372    |
| Ndb_api_trans_start_count_session          | 1      |
| Ndb_api_trans_commit_count_session         | 1      |
| Ndb_api_trans_abort_count_session          | 0      |
| Ndb_api_trans_close_count_session          | 1      |
| Ndb_api_pk_op_count_session                | 1      |
| Ndb_api_uk_op_count_session                | 0      |
| Ndb_api_table_scan_count_session           | 0      |
| Ndb_api_range_scan_count_session           | 0      |
| Ndb_api_pruned_scan_count_session          | 0      |
| Ndb_api_scan_batch_count_session           | 0      |
| Ndb_api_read_row_count_session             | 1      |
| Ndb_api_trans_local_read_row_count_session | 1      |
+-----------------------------------------+--------+
18 rows in set (0.00 sec)

mysql> USE test;
Database changed
mysql> CREATE TABLE t (c INT) ENGINE NDBCLUSTER;
Query OK, 0 rows affected (0.85 sec)
```

Now you can execute a new `SHOW STATUS` statement and observe the changes, as shown here (with the changed rows highlighted in the output):

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----------------------------------------+-----------+
| Variable_name                           | Value     |
+-----------------------------------------+-----------+
| Ndb_api_wait_exec_complete_count_session   | 8         |
| Ndb_api_wait_scan_result_count_session     | 0         |
| Ndb_api_wait_meta_request_count_session    | 17        |
| Ndb_api_wait_nanos_count_session           | 706871709 |
| Ndb_api_bytes_sent_count_session           | 2376      |
| Ndb_api_bytes_received_count_session       | 3844      |
| Ndb_api_trans_start_count_session          | 4         |
| Ndb_api_trans_commit_count_session         | 4         |
```

```
| Ndb_api_trans_abort_count_session          | 0         |
| Ndb_api_trans_close_count_session          | 4         |
| Ndb_api_pk_op_count_session                | 6         |
| Ndb_api_uk_op_count_session                | 0         |
| Ndb_api_table_scan_count_session           | 0         |
| Ndb_api_range_scan_count_session           | 0         |
| Ndb_api_pruned_scan_count_session          | 0         |
| Ndb_api_scan_batch_count_session           | 0         |
| Ndb_api_read_row_count_session             | 2         |
| Ndb_api_trans_local_read_row_count_session | 1         |
+--------------------------------------------+-----------+
18 rows in set (0.00 sec)
```

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into `t`: Insert the row, then run the same `SHOW STATUS` statement used in the previous example, as shown here:

```
mysql> INSERT INTO t VALUES (100);
Query OK, 1 row affected (0.00 sec)

mysql> SHOW STATUS LIKE 'ndb_api%session%';
+--------------------------------------------+-----------+
| Variable_name                              | Value     |
+--------------------------------------------+-----------+
| Ndb_api_wait_exec_complete_count_session   | 11        |
| Ndb_api_wait_scan_result_count_session     | 6         |
| Ndb_api_wait_meta_request_count_session    | 20        |
| Ndb_api_wait_nanos_count_session           | 707370418 |
| Ndb_api_bytes_sent_count_session           | 2724      |
| Ndb_api_bytes_received_count_session       | 4116      |
| Ndb_api_trans_start_count_session          | 7         |
| Ndb_api_trans_commit_count_session         | 6         |
| Ndb_api_trans_abort_count_session          | 0         |
| Ndb_api_trans_close_count_session          | 7         |
| Ndb_api_pk_op_count_session                | 8         |
| Ndb_api_uk_op_count_session                | 0         |
| Ndb_api_table_scan_count_session           | 1         |
| Ndb_api_range_scan_count_session           | 0         |
| Ndb_api_pruned_scan_count_session          | 0         |
| Ndb_api_scan_batch_count_session           | 0         |
| Ndb_api_read_row_count_session             | 3         |
| Ndb_api_trans_local_read_row_count_session | 2         |
+--------------------------------------------+-----------+
18 rows in set (0.00 sec)
```

We can make a number of observations from these results:

- Although we created `t` with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the “before” and “after” values of `Ndb_api_pk_op_count_session`, or 6 minus 1). This reflects the creation of the hidden primary key that is a feature of all tables using the `NDB` storage engine.

- By comparing successive values for `Ndb_api_wait_nanos_count_session`, we can see that the NDB API operations implementing the `CREATE TABLE` statement waited much longer (706871709 - 820705 = 706051004 nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the `INSERT` (707370418 - 706871709 = 498709 ns or roughly .0005 second). The execution times reported for these statements in the `mysql` client correlate roughly with these figures.

  On platforms without sufficient (nanosecond) time resolution, small changes in the value of the `WaitNanosCount` NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of `Ndb_api_wait_nanos_count_session`, `Ndb_api_wait_nanos_count_slave`, or `Ndb_api_wait_nanos_count`.

- The `INSERT` statement incremented both the `ReadRowCount` and `TransLocalReadRowCount` NDB API statistics counters, as reflected

by the increased values of `Ndb_api_read_row_count_session` and `Ndb_api_trans_local_read_row_count_session`.

22.6 NDB Cluster Replication

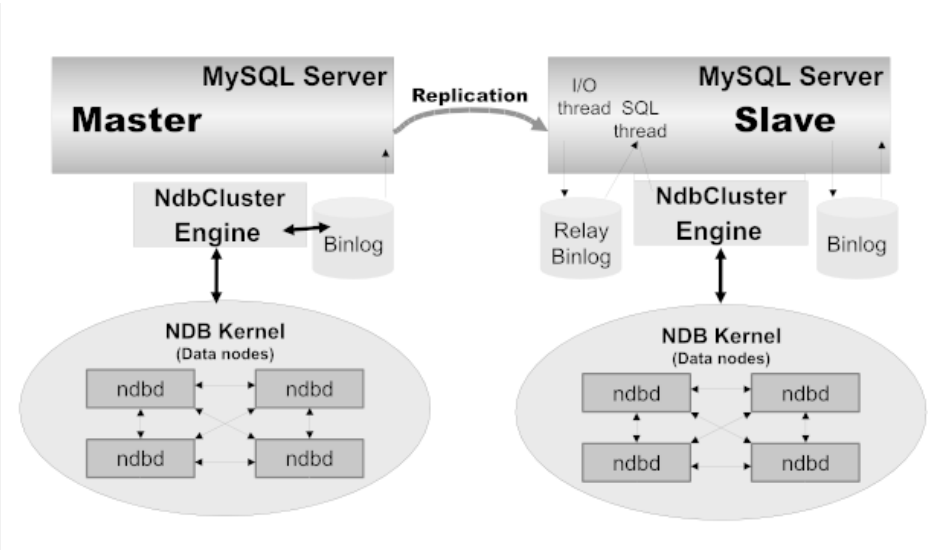
NDB Cluster supports *asynchronous replication*, more usually referred to simply as “replication”. This section explains how to set up and manage a configuration in which one group of computers operating as an NDB Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See Chapter 17, *Replication*).

Note

NDB Cluster does not support replication using GTIDs; semisynchronous replication is also not supported by the `NDB` storage engine.

Normal (non-clustered) replication involves a “master” server and a “slave” server, the master being the source of the operations and data to be replicated and the slave being the recipient of these. In NDB Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although an NDB Cluster itself depends on the `NDB` storage engine for clustering functionality, it is not necessary to use `NDB` as the storage engine for the slave's copies of the replicated tables (see Replication from NDB to other storage engines). However, for maximum availability, it is possible (and preferable) to replicate from one NDB Cluster to another, and it is this scenario that we discuss, as shown in the following figure:

Figure 22.30 NDB Cluster-to-Cluster Replication Layout



In this scenario, the replication process is one in which successive states of a master cluster are logged and saved to a slave cluster. This process is accomplished by a special thread known as the NDB binary log injector thread, which runs on each MySQL server and produces a binary log (`binlog`). This thread ensures that all changes in the cluster producing the binary log—and not just those changes that are effected through the MySQL Server—are inserted into the binary log with the correct serialization order. We refer to the MySQL replication master and replication slave servers as replication servers or replication nodes, and the data flow or line of communication between them as a *replication channel*.

For information about performing point-in-time recovery with NDB Cluster and NDB Cluster Replication, see Section 22.6.9.2, “Point-In-Time Recovery Using NDB Cluster Replication”.

NDB API _slave status variables. NDB API counters can provide enhanced monitoring capabilities on NDB Cluster replication slaves. These are implemented as NDB statistics `_slave` status variables, as seen in the output of `SHOW STATUS`, or in the results of queries against the `SESSION_STATUS` or `GLOBAL_STATUS` table in a `mysql` client session connected to a MySQL Server that is acting as a slave in NDB Cluster Replication. By comparing the values of these status variables before and after the execution of statements affecting replicated `NDB` tables, you can observe the corresponding actions taken on the NDB API level by the slave, which can be useful when monitoring or troubleshooting NDB Cluster Replication. Section 22.5.17, "NDB API Statistics Counters and Variables", provides additional information.

Replication from NDB to non-NDB tables. It is possible to replicate `NDB` tables from an NDB Cluster acting as the master to tables using other MySQL storage engines such as `InnoDB` or `MyISAM` on a slave `mysqld`. This is subject to a number of conditions; see Replication from NDB to other storage engines, and Replication from NDB to a nontransactional storage engine, for more information.

22.6.1 NDB Cluster Replication: Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the master and slave clusters, and to processes and commands run on the clusters or cluster nodes:

Table 22.413 Abbreviations used throughout this section referring to master and slave clusters, and to processes and commands run on nodes

Symbol or Abbreviation	Description (Refers to...)
`M`	The cluster serving as the (primary) replication master
`S`	The cluster acting as the (primary) replication slave
`shell`*`M`*`>`	Shell command to be issued on the master cluster
`mysql`*`M`*`>`	MySQL client command issued on a single MySQL server running as an SQL node on the master cluster
`mysql`*`M`*`*>`	MySQL client command to be issued on all SQL nodes participating in the replication master cluster
`shell`*`S`*`>`	Shell command to be issued on the slave cluster
`mysql`*`S`*`>`	MySQL client command issued on a single MySQL server running as an SQL node on the slave cluster
`mysql`*`S`*`*>`	MySQL client command to be issued on all SQL nodes participating in the replication slave cluster
`C`	Primary replication channel
`C'`	Secondary replication channel
`M'`	Secondary replication master
`S'`	Secondary replication slave

22.6.2 General Requirements for NDB Cluster Replication

A replication channel requires two MySQL servers acting as replication servers (one each for the master and slave). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there will be a total of four replication nodes, two per cluster.

Replication of an NDB Cluster as described in this section and those following is dependent on row-based replication. This means that the replication master MySQL server must be running with `--binlog-format=ROW` or `--binlog-format=MIXED`, as described in Section 22.6.6, "Starting NDB

Cluster Replication (Single Replication Channel)". For general information about row-based replication, see Section 17.2.1, "Replication Formats".

Important

If you attempt to use NDB Cluster Replication with `--binlog-format=STATEMENT`, replication fails to work properly because the `ndb_binlog_index` table on the master and the `epoch` column of the `ndb_apply_status` table on the slave are not updated (see Section 22.6.4, "NDB Cluster Replication Schema and Tables"). Instead, only updates on the MySQL server acting as the replication master propagate to the slave, and no updates from any other SQL nodes on the master cluster are replicated.

The default value for the `--binlog-format` option in NDB 8.0 is `MIXED`.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the master and slave clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=id` option, where *`id`* is a unique integer. Although it is not strictly necessary, we will assume for purposes of this discussion that all NDB Cluster binaries are of the same release version.

It is generally true in MySQL Replication that both MySQL servers (`mysqld` processes) involved must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support (see Section 17.4.2, "Replication Compatibility Between MySQL Versions"). It is due to such differences between the binaries in the NDB Cluster and MySQL Server 8.0 distributions that NDB Cluster Replication has the additional requirement that both `mysqld` binaries come from an NDB Cluster distribution. The simplest and easiest way to assure that the `mysqld` servers are compatible is to use the same NDB Cluster distribution for all master and slave `mysqld` binaries.

We assume that the slave server or cluster is dedicated to replication of the master, and that no other data is being stored on it.

All `NDB` tables being replicated must be created using a MySQL server and client. Tables and other database objects created using the NDB API (with, for example, `Dictionary::createTable()`) are not visible to a MySQL server and so are not replicated. Updates by NDB API applications to existing tables that were created using a MySQL server can be replicated.

Note

It is possible to replicate an NDB Cluster using statement-based replication. However, in this case, the following restrictions apply:

- All updates to data rows on the cluster acting as the master must be directed to a single MySQL server.
- It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
- Only changes made at the SQL level are replicated.

These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see Section 17.2.1.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication", for more specific information concerning the differences between the two replication formats.

22.6.3 Known Issues in NDB Cluster Replication

This section discusses known problems or issues when using replication with NDB Cluster 8.0.

Loss of master-slave connection. A loss of connection can occur either between the replication master SQL node and the replication slave SQL node, or between the replication master SQL node and the data nodes in the master cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflow of data node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the `MaxBufferedEpochs` and `TimeBetweenEpochs` configuration parameters). If this occurs, *it is entirely possible for new data to be inserted into the master cluster without being recorded in the replication master's binary log*. For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the slave cluster synchronized with the master. NDB Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

The replication master issues a “gap” event when connecting or reconnecting to the master cluster. (A gap event is a type of “incident event,” which indicates an incident that occurs that affects the contents of the database but that cannot easily be represented as a set of changes. Examples of incidents are server crashes, database resynchronization, (some) software updates, and (some) hardware changes.) When the slave encounters a gap in the replication log, it stops with an error message. This message is available in the output of `SHOW SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See Section 22.6.8, “Implementing Failover with NDB Cluster Replication”, for more information about what to do in such circumstances.

Important

Because NDB Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the slave server or cluster, then you must set up multiple replication lines, monitor the master `mysqld` on the primary replication line, and be prepared fail over to a secondary line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see Section 22.6.7, “Using Two Replication Channels for NDB Cluster Replication”, and Section 22.6.8, “Implementing Failover with NDB Cluster Replication”.

However, if you are replicating from a standalone MySQL server to an NDB Cluster, one channel is usually sufficient.

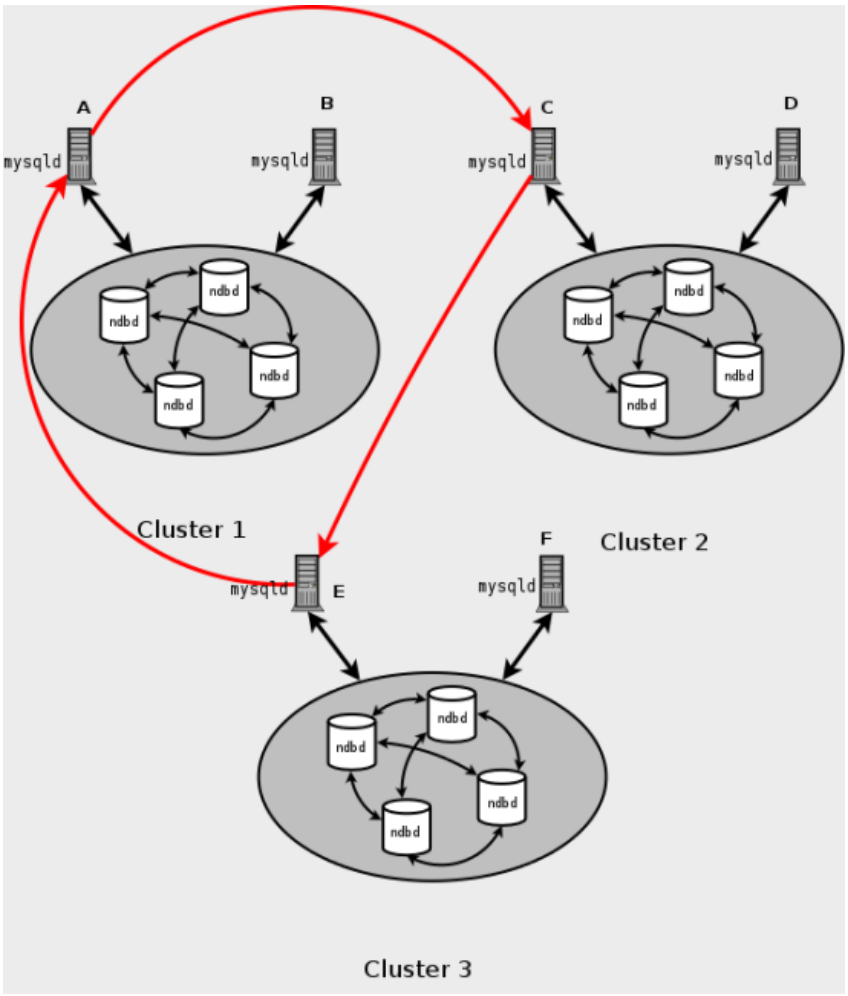
Circular replication. NDB Cluster Replication supports circular replication, as shown in the next example. The replication setup involves three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1, thus completing the circle. Each NDB Cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all masters and slaves are the same
- All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates` option

This type of circular replication setup is shown in the following diagram:

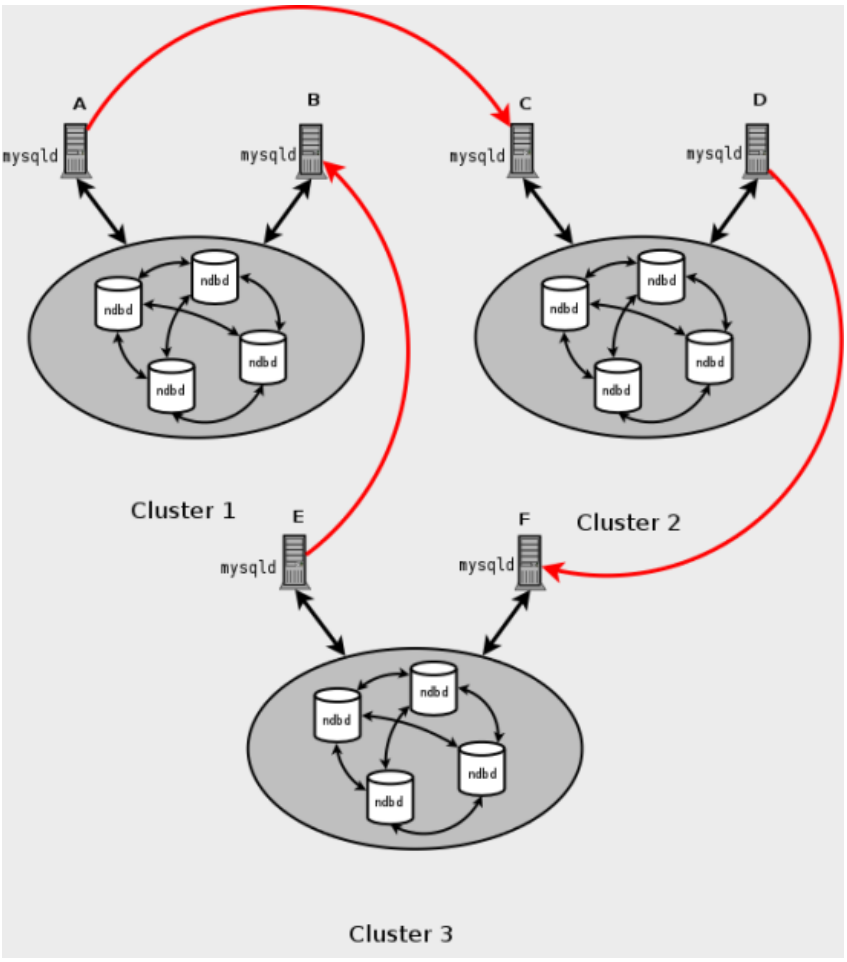
Figure 22.31 NDB Cluster Circular Replication With All Masters As Slaves



In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It should also be possible to set up circular replication in which not all master SQL nodes are also slaves, as shown here:

Figure 22.32 NDB Cluster Circular Replication Where Not All Masters Are Slaves



In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates`. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

Note

The `NDB` storage engine uses *idempotent execution mode*, which suppresses duplicate-key and other errors that otherwise break circular replication of NDB Cluster. This is equivalent to setting the global `slave_exec_mode` system variable to `IDEMPOTENT`, although this is not necessary in NDB Cluster replication, since NDB Cluster sets this variable automatically and ignores any attempts to set it explicitly.

NDB Cluster replication and primary keys. In the event of a node failure, errors in replication of `NDB` tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all `NDB` tables being replicated have primary keys.

NDB Cluster Replication and Unique Keys. In older versions of NDB Cluster, operations that updated values of unique key columns of `NDB` tables could result in duplicate-key errors when replicated. This issue is solved for replication between `NDB` tables by deferring unique key checks until after all table row updates have been performed.

Deferring constraints in this way is currently supported only by NDB. Thus, updates of unique keys when replicating from NDB to a different storage engine such as MyISAM or InnoDB are still not supported.

The problem encountered when replicating without deferred checking of unique key updates can be illustrated using NDB table such as t, is created and populated on the master (and replicated to a slave that does not support deferred unique key updates) as shown here:

```
CREATE TABLE t (
    p INT PRIMARY KEY,
    c INT,
    UNIQUE KEY u (c)
)   ENGINE NDB;

INSERT INTO t
    VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following UPDATE statement on t succeeded on the master, since the rows affected are processed in the order determined by the ORDER BY option, performed over the entire table:

```
UPDATE t SET c = c - 1 ORDER BY p;
```

However, the same statement failed with a duplicate key error or other constraint violation on the slave, because the ordering of the row updates was done for one partition at a time, rather than for the table as a whole.

Note

Every NDB table is implicitly partitioned by key when it is created. See Section 23.2.5, “KEY Partitioning”, for more information.

GTIDs not supported. Replication using global transaction IDs is not compatible with the NDB storage engine, and is not supported. Enabling GTIDs is likely to cause NDB Cluster Replication to fail.

Multithreaded slaves not supported. NDB Cluster does not support multithreaded slaves, and setting related system variables such as slave_parallel_workers, slave_checkpoint_group, and slave_checkpoint_group (or the equivalent mysqld startup options) has no effect.

This is because the slave may not be able to separate transactions occurring in one database from those in another if they are written within the same epoch. In addition, every transaction handled by the NDB storage engine involves at least two databases—the target database and the mysql system database—due to the requirement for updating the mysql.ndb_apply_status table (see Section 22.6.4, “NDB Cluster Replication Schema and Tables”). This in turn breaks the requirement for multithreading that the transaction is specific to a given database.

Restarting with --initial. Restarting the cluster with the --initial option causes the sequence of GCI and epoch numbers to start over from 0. (This is generally true of NDB Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the RESET MASTER and RESET SLAVE statements to clear the invalid ndb_binlog_index and ndb_apply_status tables, respectively.

Replication from NDB to other storage engines. It is possible to replicate an NDB table on the master to a table using a different storage engine on the slave, taking into account the restrictions listed here:

- Multi-master and circular replication are not supported (tables on both the master and the slave must use the NDB storage engine for this to work).
- Using a storage engine which does not perform binary logging for slave tables requires special handling.
- Use of a nontransactional storage engine for slave tables also requires special handling.

- The master `mysqld` must be started with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`.

The next few paragraphs provide additional information about each of the issues just described.

Multiple masters not supported when replicating NDB to other storage engines. For replication from `NDB` to a different storage engine, the relationship between the two databases must be a simple master-slave one. This means that circular or master-master replication is not supported between NDB Cluster and other storage engines.

In addition, it is not possible to configure more than one replication channel when replicating between `NDB` and a different storage engine. (However, an NDB Cluster database *can* simultaneously replicate to multiple slave NDB Cluster databases.) If the master uses `NDB` tables, it is still possible to have more than one MySQL Server maintain a binary log of all changes; however, for the slave to change masters (fail over), the new master-slave relationship must be explicitly defined on the slave.

Replicating NDB to a slave storage engine that does not perform binary logging. If you attempt to replicate from an NDB Cluster to a slave that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error `Binary logging not possible ... Statement cannot be written atomically since more than one engine involved and at least one engine is self-logging` (Error `1595`). It is possible to work around this issue in one of the following ways:

- **Turn off binary logging on the slave.** This can be accomplished by setting `sql_log_bin = 0`.
- **Change the storage engine used for the mysql.ndb_apply_status table.** Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the slave. It is safe to do this when using a non-`NDB` storage engine on the slave, since you do not then need to worry about keeping multiple slave SQL nodes synchronized.
- **Filter out changes to the mysql.ndb_apply_status table on the slave.** This can be done by starting the slave SQL node with `--replicate-ignore-table=mysql.ndb_apply_status`. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` option instead.

Important

You should *not* disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table when replicating from one NDB Cluster to another. See Replication and binary log filtering rules with replication between NDB Clusters, for details.

Replication from NDB to a nontransactional storage engine. When replicating from `NDB` to a nontransactional storage engine such as `MyISAM`, you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these by using `--ndb-log-update-as-write=0`, which forces updates to be logged as writes (rather than as updates).

Replication and binary log filtering rules with replication between NDB Clusters. If you are using any of the options `--replicate-do-*`, `--replicate-ignore-*`, `--binlog-do-db`, or `--binlog-ignore-db` to filter databases or tables being replicated, care must be taken not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between NDB Clusters to operate properly. In particular, you must keep in mind the following:

1. Using `--replicate-do-db=`*`db_name`* (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that *only* tables in database *`db_name`* are replicated. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on slaves.

Using `--binlog-do-db=db_name` (and no other `--binlog-do-db` options) means that changes *only* to tables in database *db_name* are written to the binary log. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on slaves.

2. Using `--replicate-ignore-db=mysql` means that no tables in the `mysql` database are replicated. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

   Using `--binlog-ignore-db=mysql` means that no changes to tables in the `mysql` database are written to the binary log. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

You should also remember that each replication rule requires the following:

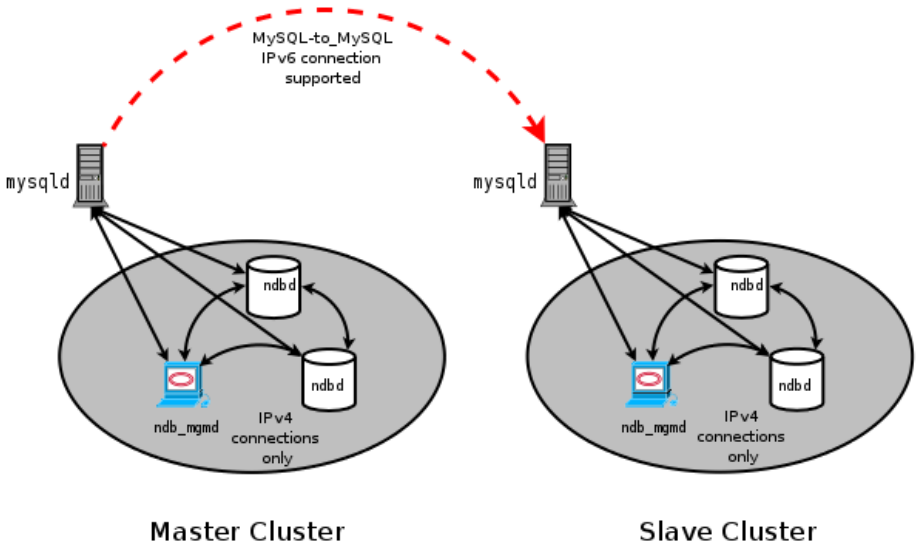
1. Its own `--replicate-do-*` or `--replicate-ignore-*` option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see Section 17.1.6, “Replication and Binary Logging Options and Variables”.

2. Its own `--binlog-do-db` or `--binlog-ignore-db` option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see Section 5.4.4, “The Binary Log”.

If you are replicating an NDB Cluster to a slave that uses a storage engine other than `NDB`, the considerations just given previously may not apply, as discussed elsewhere in this section.

NDB Cluster Replication and IPv6. Currently, the NDB API and MGM API do not support IPv6. However, MySQL Servers—including those acting as SQL nodes in an NDB Cluster —can use IPv6 to contact other MySQL Servers. This means that you can replicate between NDB Clusters using IPv6 to connect the master and slave SQL nodes as shown by the dotted arrow in the following diagram:

Figure 22.33 Replication Between SQL Nodes Connected Using IPv6



However, all connections originating *within* the NDB Cluster —represented in the preceding diagram by solid arrows—must use IPv4. In other words, all NDB Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster.

Since there is currently no support in the NDB and MGM APIs for IPv6, any applications written using these APIs must also make all connections using IPv4.

Attribute promotion and demotion. NDB Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion in NDB Cluster, see Row-based replication: attribute promotion and demotion.

`NDB`, unlike `InnoDB` or `MyISAM`, does not write changes to virtual columns to the binary log; however, this has no detrimental effects on NDB Cluster Replication or replication between `NDB` and other storage engines. Changes to stored generated columns are logged.

22.6.4 NDB Cluster Replication Schema and Tables

Replication in NDB Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and the replication slave (whether the slave is a single server or a cluster). These tables are created during the MySQL installation process, and include a table for storing the binary log's indexing data. Since the `ndb_binlog_index` table is local to each MySQL server and does not participate in clustering, it uses the `InnoDB` storage engine. This means that it must be created separately on each `mysqld` participating in the master cluster. (However, the binary log itself contains updates from all MySQL servers in the cluster to be replicated.) This table is defined as follows:

```
CREATE TABLE `ndb_binlog_index` (
    `Position` BIGINT(20) UNSIGNED NOT NULL,
    `File` VARCHAR(255) NOT NULL,
    `epoch` BIGINT(20) UNSIGNED NOT NULL,
    `inserts` INT(10) UNSIGNED NOT NULL,
    `updates` INT(10) UNSIGNED NOT NULL,
    `deletes` INT(10) UNSIGNED NOT NULL,
    `schemaops` INT(10) UNSIGNED NOT NULL,
    `orig_server_id` INT(10) UNSIGNED NOT NULL,
    `orig_epoch` BIGINT(20) UNSIGNED NOT NULL,
    `gci` INT(10) UNSIGNED NOT NULL,
    `next_position` bigint(20) unsigned NOT NULL,
    `next_file` varchar(255) NOT NULL,
    PRIMARY KEY (`epoch`,`orig_server_id`,`orig_epoch`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;
```

Note

If you are upgrading from an old release (prior to NDB 7.5.2), perform the MySQL upgrade procedure and ensure that the system tables are upgraded. (As of MySQL 8.0.16, start the server with the `--upgrade=FORCE` option. Prior to MySQL 8.0.16, invoke `mysql_upgrade` with the `--force` and `--upgrade-system-tables` options after starting the server.) The system table upgrade causes an `ALTER TABLE ... ENGINE=INNODB` statement to be executed for this table. Use of the `MyISAM` storage engine for this table continues to be supported for backward compatibility.

`ndb_binlog_index` may require additional disk space after being converted to `InnoDB`. If this becomes an issue, you may be able to conserve space by using an `InnoDB` tablespace for this table, changing its `ROW_FORMAT` to `COMPRESSED`, or both. For more information, see Section 13.1.21, “CREATE TABLESPACE Syntax”, and Section 13.1.20, “CREATE TABLE Syntax”, as well as Section 15.6.3, “Tablespaces”.

The size of this table is dependent on the number of epochs per binary log file and the number of binary log files. The number of epochs per binary log file normally depends on the amount of binary log

generated per epoch and the size of the binary log file, with smaller epochs resulting in more epochs per file. You should be aware that empty epochs produce inserts to the `ndb_binlog_index` table, even when the `--ndb-log-empty-epochs` option is `OFF`, meaning that the number of entries per file depends on the length of time that the file is in use; that is,

```
[number of epochs per file] = [time spent per file] / TimeBetweenEpochs
```

A busy NDB Cluster writes to the binary log regularly and presumably rotates binary log files more quickly than a quiet one. This means that a "quiet" NDB Cluster with `--ndb-log-empty-epochs=ON` can actually have a much higher number of `ndb_binlog_index` rows per file than one with a great deal of activity.

When `mysqld` is started with the `--ndb-log-orig` option, the `orig_server_id` and `orig_epoch` columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server, which is useful in NDB Cluster replication setups employing multiple masters. The `SELECT` statement used to find the closest binary log position to the highest applied epoch on the slave in a multi-master setup (see Section 22.6.10, "NDB Cluster Replication: Multi-Master and Circular Replication") employs these two columns, which are not indexed. This can lead to performance issues when trying to fail over, since the query must perform a table scan, especially when the master has been running with `--ndb-log-empty-epochs=ON`. You can improve multi-master failover times by adding an index to these columns, as shown here:

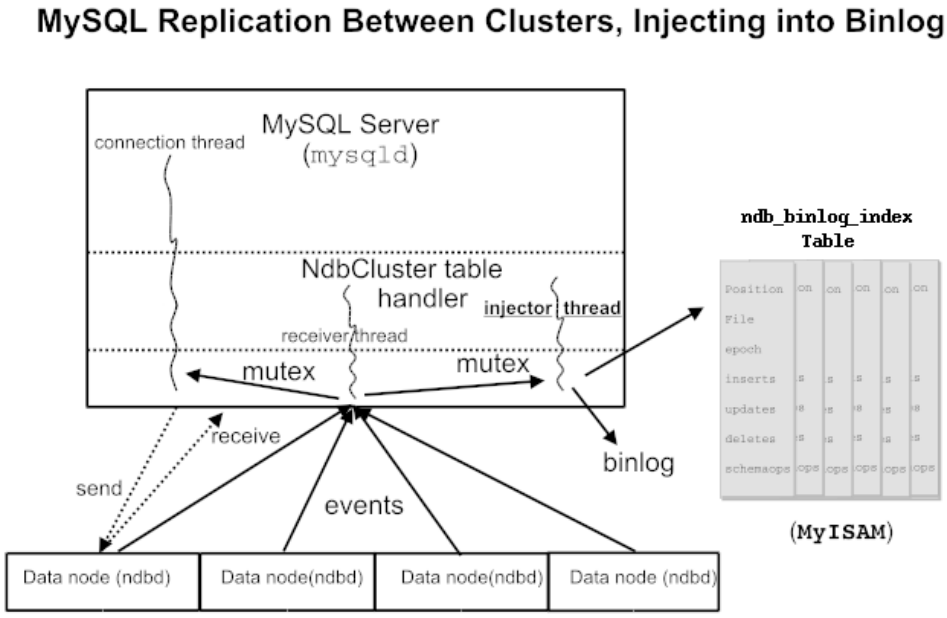
```
ALTER TABLE mysql.ndb_binlog_index
    ADD INDEX orig_lookup USING BTREE (orig_server_id, orig_epoch);
```

Adding this index provides no benefit when replicating from a single master to a single slave, since the query used to get the binary log position in such cases makes no use of `orig_server_id` or `orig_epoch`.

See Section 22.6.8, "Implementing Failover with NDB Cluster Replication", for more information about using the `next_position` and `next_file` columns.

The following figure shows the relationship of the NDB Cluster replication master server, its binary log injector thread, and the `mysql.ndb_binlog_index` table.

Figure 22.34 The Replication Master Cluster



An additional table, named `ndb_apply_status`, is used to keep a record of the operations that have been replicated from the master to the slave. Unlike the case with `ndb_binlog_index`, the data in this table is not specific to any one SQL node in the (slave) cluster, and so `ndb_apply_status` can use the `NDBCLUSTER` storage engine, as shown here:

```
CREATE TABLE `ndb_apply_status` (
    `server_id`   INT(10) UNSIGNED NOT NULL,
    `epoch`       BIGINT(20) UNSIGNED NOT NULL,
    `log_name`    VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL,
    `start_pos`   BIGINT(20) UNSIGNED NOT NULL,
    `end_pos`     BIGINT(20) UNSIGNED NOT NULL,
    PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDBCLUSTER   DEFAULT CHARSET=latin1;
```

The `ndb_apply_status` table is populated only on slaves, which means that, on the master, this table never contains any rows; thus, there is no need to allow for `DataMemory` or `IndexMemory` to be allotted to `ndb_apply_status` there.

Because this table is populated from data originating on the master, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the slave from updating `ndb_apply_status` or the master from writing into the binary log may prevent replication between clusters from operating properly. For more information about potential problems arising from such filtering rules, see Replication and binary log filtering rules with replication between NDB Clusters.

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the `mysql` database because they should not be explicitly replicated by the user. User intervention is normally not required to create or maintain either of these tables, since both `ndb_binlog_index` and the `ndb_apply_status` are maintained by the `NDB` binary log (binlog) injector thread. This keeps the master `mysqld` process updated to changes performed by the `NDB` storage engine. The `NDB` *binlog injector thread* receives events directly from the `NDB` storage engine. The `NDB` injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the `ndb_binlog_index` table. The slave I/O thread transfers the events from the master's binary log to the slave's relay log.

However, it is advisable to check for the existence and integrity of these tables as an initial step in preparing an NDB Cluster for replication. It is possible to view event data recorded in the binary log by querying the `mysql.ndb_binlog_index` table directly on the master. This can be also be accomplished using the `SHOW BINLOG EVENTS` statement on either the replication master or slave MySQL servers. (See Section 13.7.6.2, “SHOW BINLOG EVENTS Syntax”.)

You can also obtain useful information from the output of `SHOW ENGINE NDB STATUS`.

The `ndb_schema` table is used to track schema changes made to `NDB` tables. It is defined as shown here:

```
CREATE TABLE ndb_schema (
    `db` VARBINARY(63) NOT NULL,
    `name` VARBINARY(63) NOT NULL,
    `slock` BINARY(32) NOT NULL,
    `query` BLOB NOT NULL,
    `node_id` INT UNSIGNED NOT NULL,
    `epoch` BIGINT UNSIGNED NOT NULL,
    `id` INT UNSIGNED NOT NULL,
    `version` INT UNSIGNED NOT NULL,
    `type` INT UNSIGNED NOT NULL,
    PRIMARY KEY USING HASH (db,name)
) ENGINE=NDB   DEFAULT CHARSET=latin1;
```

Unlike the two tables previously mentioned in this section, the `ndb_schema` table is not visible either to MySQL `SHOW` statements, or in any `INFORMATION_SCHEMA` tables; however, it can be seen in the output of `ndb_show_tables`, as shown here:

```
shell> ndb_show_tables -t 2
id    type                 state    logging database     schema   name
4     UserTable            Online   Yes     mysql        def      ndb_apply_status
5     UserTable            Online   Yes     ndbworld     def      city
6     UserTable            Online   Yes     ndbworld     def      country
3     UserTable            Online   Yes     mysql        def      NDB$BLOB_2_3
7     UserTable            Online   Yes     ndbworld     def      countrylanguage
2     UserTable            Online   Yes     mysql        def      ndb_schema

NDBT_ProgramExit: 0 - OK
```

It is also possible to `SELECT` from this table in `mysql` and other MySQL client applications, as shown here:

```
mysql> SELECT * FROM mysql.ndb_schema WHERE name='city' \G
*************************** 1. row ***************************
     db: ndbworld
   name: city
  slock:
  query: alter table City engine=ndb
node_id: 4
  epoch: 0
     id: 0
version: 0
   type: 7
1 row in set (0.00 sec)
```

This can sometimes be useful when debugging applications.

Note

When performing schema changes on `NDB` tables, applications should wait until the `ALTER TABLE` statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

If the `ndb_apply_status` table or the `ndb_schema` table does not exist on the slave, `ndb_restore` re-creates the missing table or tables (Bug #14612).

Conflict resolution for NDB Cluster Replication requires the presence of an additional `mysql.ndb_replication` table. Currently, this table must be created manually. For information about how to do this, see Section 22.6.11, “NDB Cluster Replication Conflict Resolution”.

22.6.5 Preparing the NDB Cluster for Replication

Preparing the NDB Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see Section 22.6.2, “General Requirements for NDB Cluster Replication”).
2. Create a slave account on the master Cluster with the appropriate privileges:

   ```
   mysqlM> GRANT REPLICATION SLAVE
        -> ON *.* TO 'slave_user'@'slave_host'
        -> IDENTIFIED BY 'slave_password';
   ```

   In the previous statement, *`slave_user`* is the slave account user name, *`slave_host`* is the host name or IP address of the replication slave, and *`slave_password`* is the password to assign to this account.

   For example, to create a slave user account with the name `myslave`, logging in from the host named `rep-slave`, and using the password `53cr37`, use the following `GRANT` statement:

   ```
   mysqlM> GRANT REPLICATION SLAVE
   ```

```
    -> ON *.* TO 'myslave'@'rep-slave'
    -> IDENTIFIED BY '53cr37';
```

For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication slave account.

3. Configure the slave to use the master. Using the MySQL Monitor, this can be accomplished with the `CHANGE MASTER TO` statement:

```
mysqlS> CHANGE MASTER TO
    -> MASTER_HOST='master_host',
    -> MASTER_PORT=master_port,
    -> MASTER_USER='slave_user',
    -> MASTER_PASSWORD='slave_password';
```

In the previous statement, *`master_host`* is the host name or IP address of the replication master, *`master_port`* is the port for the slave to use for connecting to the master, *`slave_user`* is the user name set up for the slave on the master, and *`slave_password`* is the password set for that user account in the previous step.

For example, to tell the slave to replicate from the MySQL server whose host name is `rep-master`, using the replication slave account created in the previous step, use the following statement:

```
mysqlS> CHANGE MASTER TO
    -> MASTER_HOST='rep-master',
    -> MASTER_PORT=3306,
    -> MASTER_USER='myslave',
    -> MASTER_PASSWORD='53cr37';
```

For a complete list of options that can be used with this statement, see Section 13.4.2.1, “CHANGE MASTER TO Syntax”.

To provide replication backup capability, you also need to add an `--ndb-connectstring` option to the slave's `my.cnf` file prior to starting the replication process. See Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”, for details.

For additional options that can be set in `my.cnf` for replication slaves, see Section 17.1.6, “Replication and Binary Logging Options and Variables”.

4. If the master cluster is already in use, you can create a backup of the master and load this onto the slave to cut down on the amount of time required for the slave to synchronize itself with the master. If the slave is also running NDB Cluster, this can be accomplished using the backup and restore procedure described in Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”.

```
ndb-connectstring=management_host[:port]
```

In the event that you are *not* using NDB Cluster on the replication slave, you can create a backup with this command on the replication master:

```
shellM> mysqldump --master-data=1
```

Then import the resulting data dump onto the slave by copying the dump file over to the slave. After this, you can use the `mysql` client to import the data from the dumpfile into the slave database as shown here, where *`dump_file`* is the name of the file that was generated using `mysqldump` on the master, and *`db_name`* is the name of the database to be replicated:

```
shellS> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see Section 4.5.4, “`mysqldump` — A Database Backup Program”.

Note

If you copy the data to the slave in this fashion, you should make sure that the slave is started with the `--skip-slave-start` option on the command line, or else include `skip-slave-start` in the slave's `my.cnf` file to keep it from trying to connect to the master to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication master is configured with a unique server ID, and with binary logging enabled, using the row format. (See Section 17.2.1, “Replication Formats”.) These options can be set either in the master server's `my.cnf` file, or on the command line when starting the master `mysqld` process. See Section 22.6.6, “Starting NDB Cluster Replication (Single Replication Channel)”, for information regarding the latter option.

22.6.6 Starting NDB Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting NDB Cluster replication using a single replication channel.

1. Start the MySQL replication master server by issuing this command:

```
shellM> mysqld --ndbcluster --server-id=id \
        --log-bin &
```

In the previous statement, *`id`* is this server's unique ID (see Section 22.6.2, “General Requirements for NDB Cluster Replication”). This starts the server's `mysqld` process with binary logging enabled using the proper logging format.

Note

You can also start the master with `--binlog-format=MIXED`, in which case row-based replication is used automatically when replicating between clusters. `STATEMENT` based binary logging is not supported for NDB Cluster Replication (see Section 22.6.2, “General Requirements for NDB Cluster Replication”).

2. Start the MySQL replication slave server as shown here:

```
shellS> mysqld --ndbcluster --server-id=id &
```

In the command just shown, *`id`* is the slave server's unique ID. It is not necessary to enable logging on the replication slave.

Note

You should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the slave server's `my.cnf` file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START SLAVE` statement has been issued, as explained in Step 4 below.

3. It is necessary to synchronize the slave server with the master server's replication binary log. If binary logging has not previously been running on the master, run the following statement on the slave:

```
```

```
mysqlS> CHANGE MASTER TO
     -> MASTER_LOG_FILE='',
     -> MASTER_LOG_POS=4;
```

This instructs the slave to begin reading the master's binary log from the log's starting point. Otherwise—that is, if you are loading data from the master using a backup—see Section 22.6.8, “Implementing Failover with NDB Cluster Replication”, for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

4. Finally, you must instruct the slave to begin applying replication by issuing this command from the `mysql` client on the replication slave:

```
mysqlS> START SLAVE;
```

This also initiates the transmission of replication data from the master to the slave.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in Section 22.6.7, “Using Two Replication Channels for NDB Cluster Replication”.

It is also possible to improve cluster replication performance by enabling *batched updates*. This can be accomplished by setting the `slave_allow_batching` system variable on the slave `mysqld` processes. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in 32 KB batches, which can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

Note

Slave batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), slave batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether slave batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```
mysql> SHOW VARIABLES LIKE 'slave%';
+---------------------------+-------+
| Variable_name             | Value |
+---------------------------+-------+
| slave_allow_batching      | ON    |
| slave_compressed_protocol | OFF   |
| slave_load_tmpdir         | /tmp  |
| slave_net_timeout         | 3600  |
| slave_skip_errors         | OFF   |
| slave_transaction_retries | 10    |
+---------------------------+-------+
```

```
6 rows in set (0.00 sec)
```

22.6.7 Using Two Replication Channels for NDB Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two masters for the master cluster and two slave servers for the slave cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

Table 22.414 NDB Cluster replication servers described in the text

Server ID	Description
1	Master - primary replication channel (*M*)
2	Master - secondary replication channel (*M'*)
3	Slave - primary replication channel (*S*)
4	Slave - secondary replication channel (*S'*)

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication masters must be started, followed by those for the primary and secondary slaves. Then the replication processes may be initiated by issuing the `START SLAVE` statement on each of the slaves. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication master:

```
shellM> mysqld --ndbcluster --server-id=1 \
               --log-bin &
```

2. Start the secondary replication master:

```
shellM'> mysqld --ndbcluster --server-id=2 \
               --log-bin &
```

3. Start the primary replication slave server:

```
shellS> mysqld --ndbcluster --server-id=3 \
               --skip-slave-start &
```

4. Start the secondary replication slave:

```
shellS'> mysqld --ndbcluster --server-id=4 \
                --skip-slave-start &
```

5. Finally, initiate replication on the primary channel by executing the `START SLAVE` statement on the primary slave as shown here:

```
mysqlS> START SLAVE;
```

Warning

Only the primary channel is to be started at this point. The secondary replication channel is to be started only in the event that the primary replication channel fails, as described in Section 22.6.8, “Implementing Failover with NDB Cluster Replication”. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

As mentioned previously, it is not necessary to enable binary logging on replication slaves.

22.6.8 Implementing Failover with NDB Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the `ndb_apply_status` table on the slave cluster, which can be found using the following query:

```
mysqlS'> SELECT @latest:=MAX(epoch)
      ->        FROM mysql.ndb_apply_status;
```

In a circular replication topology, with a master and a slave running on each host, when you are using `ndb_log_apply_status=1`, NDB Cluster epochs are written in the slave binary logs. This means that the `ndb_apply_status` table contains information for the slave on this host as well as for any other host which acts as a slave of the master running on this host.

In this case, you need to determine the latest epoch on this slave to the exclusion of any epochs from any other slaves in this slave's binary log that were not listed in the `IGNORE_SERVER_IDS` options of the `CHANGE MASTER TO` statement used to set up this slave. The reason for excluding such epochs is that rows in the `mysql.ndb_apply_status` table whose server IDs have a match in the `IGNORE_SERVER_IDS` list used with the CHANGE MASTER TO statement used to prepare this slave's master are also considered to be from local servers, in addition to those having the slave's own server ID. You can retrieve this list as `Replicate_Ignore_Server_Ids` from the output of `SHOW SLAVE STATUS`. We assume that you have obtained this list and are substituting it for *`ignore_server_ids`* in the query shown here, which like the previous version of the query, selects the greatest epoch into a variable named `@latest`:

```
mysqlS'> SELECT @latest:=MAX(epoch)
      ->        FROM mysql.ndb_apply_status
      ->        WHERE server_id NOT IN (ignore_server_ids);
```

In some cases, it may be simpler or more efficient (or both) to use a list of the server IDs to be included and `server_id IN server_id_list` in the `WHERE` condition of the preceding query.

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the `ndb_binlog_index` table on the master cluster.

You can use the following query to obtain the needed records from the master's `ndb_binlog_index` table:

```
mysqlM'> SELECT
      ->     @file:=SUBSTRING_INDEX(next_file, '/', -1),
      ->     @pos:=next_position
      -> FROM mysql.ndb_binlog_index
      -> WHERE epoch >= @latest
      -> ORDER BY epoch ASC LIMIT 1;
```

These are the records saved on the master since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be “plugged in” to the second query manually or in application code.

Important

You must ensure that the slave `mysqld` is started with `--slave-skip-errors=ddl_exist_errors` before executing `START SLAVE`. Otherwise, replication may stop with duplicate DDL errors.

3. Now it is possible to synchronize the secondary channel by running the following query on the secondary slave server:

```
mysqlS'> CHANGE MASTER TO
      ->     MASTER_LOG_FILE='@file',
      ->     MASTER_LOG_POS=@pos;
```

   Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using application code that can access both of the servers involved.

Note

`@file` is a string value such as `'/var/log/mysql/replication-master-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must *not* be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary slave `mysqld`:

```
mysqlS'> START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this will depend upon the reasons for which the primary channel failed.

Warning

The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

If the failure is limited to a single server, it should (in theory) be possible to replicate from *M* to *S'*, or from *M'* to *S*; however, this has not yet been tested.

22.6.9 NDB Cluster Backups With NDB Cluster Replication

This section discusses making backups and restoring from them using NDB Cluster replication. We assume that the replication servers have already been configured as covered previously (see Section 22.6.5, “Preparing the NDB Cluster for Replication”, and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.

   - **Method A.** This method requires that the cluster backup process was previously enabled on the master server, prior to starting the replication process. This can be done by including the following line in a `[mysql_cluster]` section in the `my.cnf file`, where *`management_host`* is the IP address or host name of the `NDB` management server for the master cluster, and *`port`* is the management server's port number:

```
ndb-connectstring=management_host[:port]
```

Note

The port number needs to be specified only if the default port (1186) is not being used. See Section 22.2.4, “Initial Configuration of NDB Cluster”, for more information about ports and port allocation in NDB Cluster.

In this case, the backup can be started by executing this statement on the replication master:

```
shellM> ndb_mgm -e "START BACKUP"
```

- **Method B.** If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the `NDB` management client as part of the `START BACKUP` command. This can be done as shown here, where *`management_host`* and *`port`* are the host name and port number of the management server:

  ```
  shellM> ndb_mgm management_host:port -e "START BACKUP"
  ```

  In our scenario as outlined earlier (see Section 22.6.5, “Preparing the NDB Cluster for Replication”), this would be executed as follows:

  ```
  shellM> ndb_mgm rep-master:1186 -e "START BACKUP"
  ```

2. Copy the cluster backup files to the slave that is being brought on line. Each system running an `ndbd` process for the master cluster will have cluster backup files located on it, and *all* of these files must be copied to the slave to ensure a successful restore. The backup files can be copied into any directory on the computer where the slave management host resides, so long as the MySQL and NDB binaries have read permissions in that directory. In this case, we will assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

   It is not necessary that the slave cluster have the same number of `ndbd` processes (data nodes) as the master; however, it is highly recommended this number be the same. It *is* necessary that the slave be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the slave cluster that are present on the master cluster that are to be replicated to the slave.

   Important

   A `CREATE DATABASE` (or `CREATE SCHEMA`) statement corresponding to each database to be replicated must be executed on each SQL node in the slave cluster.

4. Reset the slave cluster using this statement in the MySQL Monitor:

   ```
   mysqlS> RESET SLAVE;
   ```

5. You can now start the cluster restoration process on the replication slave using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata:

   ```
   shellS> ndb_restore -c slave_host:port -n node-id \
          -b backup-id -m -r dir
   ```

   `dir` is the path to the directory where the backup files have been placed on the replication slave. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

   For restoring from a master cluster with four data nodes (as shown in the figure in Section 22.6, “NDB Cluster Replication”) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the slave might look like this:

   ```
   ```

```
shellS> ndb_restore -c rep-slave:1186 -n 2 -b 1 -m \
        -r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 3 -b 1 \
        -r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 4 -b 1 \
        -r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 5 -b 1 -e \
        -r ./var/BACKUPS/BACKUP-1
```

Important

The `-e` (or `--restore_epoch`) option in the final invocation of `ndb_restore` in this example is required in order that the epoch is written to the slave `mysql.ndb_apply_status`. Without this information, the slave will not be able to synchronize properly with the master. (See Section 22.4.23, “`ndb_restore` — Restore an NDB Cluster Backup”.)

6. Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the slave (as discussed in Section 22.6.8, “Implementing Failover with NDB Cluster Replication”):

```
mysqlS> SELECT @latest:=MAX(epoch)
        FROM mysql.ndb_apply_status;
```

7. Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the master's `mysql.ndb_binlog_index` table using the query shown here:

```
mysqlM> SELECT
     ->     @file:=SUBSTRING_INDEX(File, '/', -1),
     ->     @pos:=Position
     -> FROM mysql.ndb_binlog_index
     -> WHERE epoch >= @latest
     -> ORDER BY epoch ASC LIMIT 1;
```

   In the event that there is currently no replication traffic, you can get this information by running `SHOW MASTER STATUS` on the master and using the value in the `Position` column for the file whose name has the suffix with the greatest value for all files shown in the `File` column. However, in this case, you must determine this and supply it in the next step manually or by parsing the output with a script.

8. Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the slave's `mysql` client:

```
mysqlS> CHANGE MASTER TO
     ->     MASTER_LOG_FILE='@file',
     ->     MASTER_LOG_POS=@pos;
```

9. Now that the slave “knows” from what point in which binary log file to start reading data from the master, you can cause the slave to begin replicating with this standard MySQL statement:

```
mysqlS> START SLAVE;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary master and slave for those of the primary master and slave replication servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see Section 22.5.3, “Online Backup of NDB Cluster”.

22.6.9.1 NDB Cluster Replication: Automating Synchronization of the Replication Slave to the Master Binary Log

It is possible to automate much of the process described in the previous section (see Section 22.6.9, “NDB Cluster Backups With NDB Cluster Replication”). The following Perl script `reset-slave.pl` serves as an example of how you can do this.

```
#!/user/bin/perl -w

#  file: reset-slave.pl

22.6.9.2 Point-In-Time Recovery Using NDB Cluster Replication
